A.1.2 Planning Authority

The local planning authority is Donegal County Council, however the application has been sent to An Bord Pleanala for planning.

A.1.3 Sanitary Authority

The local sanitary authority is Donegal County Council.

A.I.4 Location of Facility

Donegal County Council are proposing to develop a landfill facility at Meenaboll, approximately 17Km west of Letterkenny, in the mid Donegal area. The National Grid Reference for the facility is E199480 N409330.

A.1.5 Nature of the Facility

The proposed site has to be seen in the context of the Donegal Waste Management Plan, which was the subject of widespread public consultation, and adopted by the Council in 2000.

This plan identified the need for an additional 2-4 landfill facilities in Donegal, to provide secure long term disposal for the County. A detailed site selection process was undertaken on this basis in accordance with the EPA's Draft Landfill Manual on Site Selection. Resulting from this it is proposed to construct a landfill site at Meenaboll.

The proposed facility, which covers an area of 14.5 hectares, of which 4.5 hectares is for landfilling, would be developed and operated on a 'containment basis', in accordance with the standards set out in Council Directive (1999/31/EC) on the Landfilling of Waste, other wise known as the Landfill Directive. The remainder of the land will be utilised for site infrastructure, environmental monitoring and visual screening.

The site, which will accept up to 24,000 tonnes per annum for disposal at the landfill, will be classified as a non-hazardous landfill to accept household, commercial and industrial wastes from within the County. Waste will be accepted for recovery at the Civic Amenity Facility to be provided on site and will cater for household hazardous wastes.

The landfill would be operational for 20 years, and along with the extension to Ballynacarrick landfill site in South Donegal, represents an important stage in meeting the targets set out in the Waste Management Plan.

The Council are also considering the development of recycling and recovery facilities within the County, in accordance with the Waste Management Plan. It is recognised that one option would be to provide an integrated waste management facility at the site, incorporating materials recovery and recycling infrastructure, with the disposal of residues to the landfill. Further consideration will be given to this during the review of the Waste Management Plan in 2005. Any such development at the site would be subject to further statutory applications for approval.

The site is located in an area of recently felled coniferous forest owned by Coillte Teoranta, on the northwestern flank of Meenaboll Hill in the remote townlands of Meenaboll, Co. Donegal. The site is accessed by a county road which extends some 1.2km off the R250 Letterkenny to Glenties road at a junction situated approximately 17km to the southwest of Letterkenny. The nearest residential property to the site is located approximately 2Km from the proposed development.

The proposed facility covers an area of 14.5 hectares with the landfill area having an area of approximately 4.5 hectares, which will provide a capacity of approximately 500,000m³ of landfill void space over an estimated lifespan of 20 years. It is envisaged the landfill operations, i.e. the deposition of waste at the facility, will commence during 2006 and cease by the end of 2025.

The landfill site will be developed on a containment basis to meet the requirements of the EU Landfill Directive (1999/31/EC). The site will be lined with a composite lining system to prevent the migration

*For inspection purposes only.
Consent of copyright owner required for any other use.*

It is now accepted practice, particularly with the advent of containment sites, for landfills to be designed and operated in a series of discrete phases. The site at Meenaboll will be developed with 5 Phases. Phases 1 and 2 will be developed with one cell in each while Phases 3, 4 and 5 will consist of two cells which will be designed to allow for efficient management of the leachate. The site will be operated to standards set out by the Environmental Protection Agency. The cells will be capped, after being filled to the final permitted levels, with a low permeability capping layer thereby minimising the generation of leachate in the existing waste body. The key elements associated with the development of the site are summarised below.

The geological setting of Meenaboll Landfill site was examined by means of a desk study, walkover survey and an exploratory ground investigation.

The proposed landfill is entirely underlain by metamorphic rocks assigned to the Upper Falcarragh Pelite Formation, a sub-division of the Dalradian Supergroup. The bedrock is completely mantled by a variable thickness drift deposits comprising a lower horizon of boulder clay and an upper peat layer.

No regional faults or slides are shown to pass through the study area. The Knockateen slide as a northeast to southwest trending thrust fault, represents the nearest structural feature to the site. The fault plane is inclined to the southwest beneath the summit of Meenaboll Hill and does not extend beneath the site.

Peaty topsoils mantle the entire site area, which is associated with very poor drainage conditions, where the soils are waterlogged for most of the year. These soil conditions are only suitable for rough grazing purposes, or in the case of the study area coniferous plantation. The textural limitations of the peaty soils also inhibit attempts to improve the drainage of the material.

The development of the landfill site will inevitably lead to the disturbance and/or **loss** of the peaty topsoils over an area of 4.5 hectares. However, the **loss** of these soils would not represent a significant environmental impact as they are of limited agricultural amenity and occur extensively throughout the region.

The construction of the landfill also has the potential to destroy any features of geological interest that may exist within the site. However, no bedrock exposures, drift deposits or landforms of special geological or scientific interest exist within the study area. The construction of the landfill and resultant **loss** of prevailing geological features at the site would not therefore represent a significant environmental impact as high quality exposures occur extensively throughout the region.

A.1.6 Waste Disposal Activities Undertaken

Schedule 3

The principle class of activity proposed for the Landfill is Class 5 of the Third Schedule of the Waste Management Act (1996) namely:

‘Specially engineered landfill, including placement into lined discrete cells which are capped and isolated from one another and the environment’.

Other activities proposed for the Meenaboll Landfill Site are covered under the following classes of the Third and Fourth Schedule:

Class 1: *“Deposit on, in or under land”:*

Class 4: *“Surface impoundment, including placement of liquid or sludge discards into pits, ponds or lagoons”.*

Class 6: *“Biological treatment not referred to elsewhere in this Schedule which results in final compounds or mixtures which are disposed of by means of any activity referred to in this Schedule”.*

Class 13: *“Storage prior to submission to any activity referred to in this Schedule, other than temporary storage, pending collection, on the premises where the waste concerned is produced”.*

Schedule 4

Class 2: *“Recycling or reclamation of organic substances which are not used as solvents”.*

Class 3: *“Recycling or reclamation of metals and metal compounds”*

Class 4: *“Recycling or reclamation of other inorganic materials.”*

Class 13: *“Storage of waste intended for submission to any activity referred to in a preceding paragraph of this Schedule, other than temporary storage, pending collection, on the premises where such waste is produced”.*

A.1.7 European Waste Catalogue Codes

The following Table A1.7 provides the annual amount of waste to be accepted at the proposed Meenaboll Landfill Site.

Table A1.7.1 Annual Amount of Waste to be Accepted

| Year | Non-Hazardous Waste (tonnes per annum) | Hazardous Waste (tonnes per annum) | Total Annual Quantity of Waste (tonnes per annum) |
|---------------------------------|--|------------------------------------|---|
| 2006(Estimated 2 months input). | 4,000 | Not applicable | 4,000 |
| 2007 | 24,000 for disposal at Landfill. 1,500 for recovery at CA Site | Not applicable | 25,500 |
| 2008 | As above | Not applicable | 25,500 |
| 2009 | As above | Not applicable | 25,500 |
| 2010 | As above | Not applicable | 25,500 |
| 2011 | As above | Not applicable | 25,500 |
| 2012 | As above | Not applicable | 25,500 |
| 2013 | As above | Not applicable | 25,500 |
| 2014 | As above | Not applicable | 25,500 |
| 2015 | As above | Not applicable | 25,500 |
| 2016 | As above | Not applicable | 25,500 |
| 2017 | As above | Not applicable | 25,500 |
| 2018 | As above | Not applicable | 25,500 |
| 2019 | As above | Not applicable | 25,500 |
| 2020 | As above | Not applicable | 25,500 |
| 2021 | As above | Not applicable | 25,500 |
| 2022 | As above | Not applicable | 25,500 |
| 2023 | As above | Not applicable | 25,500 |
| 2024 | As above | Not applicable | 25,500 |
| 2025 | As above | Not applicable | 25,500 |

The European Waste Catalogue Codes for wastes to be received at the facility for disposal or recovery are as per Table A1.7.2. These are based on waste streams currently being received at Ballynacarrick Landfill Site. Other non hazardous waste wastes streams may be accepted at the facility, however the main waste stream will be mixed municipal waste.

Table A.1.7.2 Waste for Disposal at Landfill

| Type of Waste | EWC |
|---|----------|
| Mixed Municipal Waste | 20 03 01 |
| Street Cleaning | 20 03 03 |
| Mixed Packaging Waste | 1501 06 |
| Ceramics, Bricks, Tiles ,After Thermal | 10 12 08 |
| Biodegradable Kitchen and Canteen Waste | 20 01 08 |
| Construction and Demolition | 1701 07 |

Table A1.7.3 Proposed Waste Streams for Recovery at the Civic Amenity Site

| Type of Waste | EWC | Examples |
|--|-----------|---|
| Paper & Cardboard Packaging | 15 01 01 | Brown corrugated cardboard, Cereal, tissue and pizza boxes |
| Plastic Packaging | 15 01 02 | Tetra milk cartons, Plastic Mineral Bottles, Plastic Milk Bottles, Plastic Coloured Bottles, Plastic carrier bags Polystyrene |
| Metallic Packaging | 15 01 04 | Aluminium drinks cans |
| Glass Packaging | 15 01 07 | Green, Brown, Blue and clear glass |
| Paper & Cardboard Packaging | 20 01 01 | Magazines, Newspaper, Office Paper, Brochures, Books |
| Fluorescent Tubes | 20 01 21 | |
| Discarded Equipment containing CFCs | 20 01 23* | Fridges, Freezers |
| Edible oil and fat | 20 01 25 | Cooking oil |
| Oils and fat | 20 01 26 | Car engine oil |
| Paint Inks adhesives and resins containing dangerous substances. | 20 01 27* | Gloss and emulsion paint |
| Paint Inks adhesives and resins other than those mentioned in 21 01 27 | 20 01 28 | |
| Batteries and accumulators (Lead/acid, Ni/Cad or Mercury) | 20 01 33* | Car and household batteries |
| Batteries and accumulators other than those mentioned | 20 01 34 | |
| Discarded electrical and electronic equipment containing hazardous components. | 20 01 35* | Televisions, monitors, Computers, Washing Machines, Microwaves, Cookers. Mobile phone |
| Discarded electrical and electronic equipment | 20 01 36 | |
| Biodegradable Wastes (Garden and Park Waste) | 20 02 01 | |
| Mixed Municipal Waste | 20 03 01 | |

A.1.8 Raw and Ancillary Materials

Raw materials, which will be utilised in the operation of Meenaboll Landfill Site, are set out in Table A.1.8.1 below.

Table A.1.8.1 Fuel and Energy Usage

| Fuel and Energy Utilised | Annual Usage | Quantities Stored on Site |
|--------------------------|---------------------|--|
| Water | 1,000m ³ | Not applicable |
| Electricity | 21,200 kWh | Not applicable |
| Diesel | 38,000 litres | Proposal for 10,000 litre tank on site |
| Hydraulic Oil | 25 litres | Not applicable |

A.1.9 Plant, Processes, Site Operating Procedures

It is envisaged that the site will receive a maximum of 24,000 tonnes of non hazardous waste per annum. The waste will be delivered to the site by road refuse freighters operated by private waste collection companies. All operations will be carried out in accordance with the Waste Disposal Licence, which would be issued by the EPA in accordance with the Waste Management (Licensing) Regulation, 2000.

Waste will be accepted for recovery at the Civic Amenity Facility to be provided on site and will cater for household hazardous wastes.

The proposed facility covers an area of 14.5 hectares with the landfill area having an area of approximately 4.5 hectares, which will provide a capacity of approximately 500,000m³ of landfill void space over an estimated lifespan of 20 years. It is envisaged the landfill operations, i.e. the deposition of waste at the facility, will commence during 2006 and cease by the end of 2025.

Earthworks

During the development of the proposed landfill all peat and boulder clay will be stripped from the surface to the in situ rock level or below to the proposed formation levels. The excavated material will be stored on undeveloped areas of the site. The boulder clay excavated will be utilised for the construction of the perimeter bunds while it is proposed to utilise the excavate rock for producing the construction material i.e. drainage layers thereby minimising the need to import material from external sources. The disposal area will be bounded by a minimum 30m wide buffer zone.

Groundwater Drainage

The base and sides of each cell will be prepared by cutting or filling as necessary to achieve the desired profile. These will then be covered by a 300 mm deep layer of fines free crushed rock aggregate with a network of collection drains.

The base of each cell will have a minimum 1:25 gradient towards the collection sump and 1:100 in a transverse direction. The drainage blanket will intercept any groundwater seepage below the landfill, deliver it under gravity to the constructed wet lands prior to discharging to the existing watercourse i.e. Sruhanpolladoo stream to the northwest of the site.

Surface Water Drainage

In order to engineer the site it will be necessary to culvert the Sruhanpolladoo stream which runs along the northeastern boundary of the proposed site. In addition to this a surface water collection pipeline will be installed around the perimeter of the proposed landfill to collect surface water falling towards the landfill area. The surface water pipelines will join to the north of the proposed site and pass through a constructed wetland prior to discharging to the Sruhanpolladoo stream.

Containment System

The containment system is achieved by engineering the base and sides of the site using low permeability materials such as naturally occurring clays and/or synthetic geomembranes.

The containment system comprises a 2mm thick High Density Polyethylene (HDPE) geomembrane, welded to form a continuous membrane across the area of the landfill. This is underlain by a 500mm thick layer of low permeability Bentonite Enhanced Soil (BES) installed on top of a groundwater drainage blanket. The HDPE will then be covered by a protective geotextile layer and a leachate drainage blanket constructed of crushed aggregate. This blanket will provide an efficient system for the removal of any excess quantities of leachate, which may be generated.

Leachate Collection System

Leachate is produced as a result of the coupled action of the breakdown of waste material and rainfall percolating through the waste. The proposal includes the provision of a control system, designed to manage the quantities of leachate generated. A leachate collection system will be installed and this comprises a 500mm deep drainage blanket, as previously described, with 225mm diameter High Density Polyethylene (HDPE) collection pipes. The HDPE collection pipes will discharge leachate into a collection sump from where it will be pumped to a treatment tank, prior to disposal at a Waste Water Treatment Works.

The proposed leachate collection and treatment system complies with the accepted and specified standards and practices and will provide a control mechanism to ensure that there is no build up of excess leachate at the landfill.

Landfill Gas Collection System

Landfill gas is generated from the degradation of putrescible fractions within the waste. The major components of landfill gas are Methane (66%) and Carbon dioxide (33%) with a number of minor components in low concentrations.

Methane is flammable and a landfill gas collection system will be installed to prevent the build up of gas. Uncontrolled gas migration off site will be prevented by the engineered containment system.

A series of gas wells will be installed following waste infilling on the proposed site. The wells will then be connected to a permanent gas flaring unit via a HDPE collection pipe.

Power Supply

The three phase power supply in closest proximity to the site is located over 4km away and to provide the site with a three phase supply would involve the erection of pylons to carry the cables onto site. This would not be considered appropriate for the location of the proposed site and as such electricity for the operation of site equipment and plant will be generated from an on site generator. This will be enclosed in a sound proofing container and buried into the embankment adjacent to the leachate holding tanks.

Site Infrastructure

Modern landfills require a substantial amount of associated infrastructure in order to operate to current guidelines and licence requirements. This includes Site Office, Weighbridge, Wheelwash, Haul Road, Security Fencing, Leachate holding tanks, Leachate treatment facility, Waste Inspection/Quarantine area, Surface water drainage, Car parking, Landfill Gas Flare, Recycling Area, Plant Maintenance Shed, Fuel Storage Area, Electrical Generator, Settlement Ponds and Constructed Wetlands. These facilities will allow for good operational practices to be applied in respect to waste acceptance, recording, control and emplacement as well as leachate and landfill gas management.

Site Management

The site will be operational from 8.30 am to 5.00 pm Monday to Friday and 9.00 am to 1.00 pm on Saturday and will be manned by a minimum of 4 personnel. Operations may be undertaken outside these hours to facilitate emergency situations and the moving of the enclosed litter netting. Further personnel will be employed on an as required basis to deal with general maintenance of the site

The site management system procedures will be set out in the Environmental Management System, a document which defines responsibilities and site procedures. The management system will cover all operational activities of the waste acceptance and waste disposal on site, taking into account weighing of inputs, compaction and covering of wastes, control of vermin, litter, insects and birds, traffic control and the cleaning of roads. Odour control, noise control and fire prevention and control will also be incorporated into the management system.

Site personnel will be appropriately trained in health and safety matters generally and particularly on those areas that pertain to operation of a landfill facility.

Phasing

The site will be progressively infilled and restored in phases. Each phase will be filled from the base to final levels sequentially. It will be necessary to commence filling in the subsequent cell before final levels may be reached in the preceding cell. However it is envisaged that no more than two cells will be open at any one time. The site will be filled in each phase to the proposed final profile making appropriate allowances for settlement of the waste mass to ensure that the predetermined profiles can be achieved. Permanent restoration will occur at the end of each phase and landscaping works will be undertaken.

Leachate Management

The proposals for the development of the Meenaboll site allow for containment of all leachate generated at the site. This will require appropriate management throughout the life and aftercare period of the site to maintain leachate control and treatment.

Management of leachate will relate to generation, composition, control, treatment, disposal and monitoring.

Landfill Gas Management

Management procedures at Meenaboll will ensure appropriate management of landfill gas during the life and aftercare of the site. This will accommodate the changes in quantity and composition of landfill gas, which occur with time. The management procedures will ensure that uncontrolled off-site migration will not occur. Monitoring will form an important part of this process and will follow the requirements of the Waste Management Licence.

Community Liaison

A community liaison group will be established. Representatives of the local community will be invited to meet periodically with representatives of the site management to discuss progress with the development, operation and closure of the site.

A.I.10 Determination of Section 40 (4) of the Act

To comply with the requirements of the Waste Management Act 1996 as amended, the activity concerned (waste disposal by landfill) must comply with Sections 40(4)(a) to 40(4)(t).

Section 40(4)(a) of the Waste Management Act, 1996 requires that prescribed emission standards and limit values are complied with by the facility.

- ✦ **Liquid Emissions;** With respect to emissions to groundwater the appropriate standard is the EU Groundwater Directive (80/68/EEC), as implemented through legislation. The Directive requires that the direct discharge of List I substances to groundwater be prevented, and that the discharge of List II substances should be minimised. The site will be developed on a containment basis in accordance with the requirements of the Landfill Directive. Capping of the existing site will significantly reduce the volumes of leachate being created.

The proposals should prevent the discharge of List I substances to groundwater and minimise the discharge of List II substances.

Monitoring of surface and groundwater at the site will allow current and future impacts to be addressed in the context of the site development. Operation of the facility will therefore be in accordance with the Groundwater Directive.

- ✦ **Emissions to air:** A 30 day average dust deposition rate of 350 mg/m²/day (as recommended in T A Luft) at the boundary of the site will be included in the Waste Licence. Results from regular dust monitoring will be compared against these standards.

- ✦ **Noise:** The standards applicable to noise emissions at the site are as follows: BS5228 (1984 and 1987) 'Noise Control on Construction and Open Sites' Part 1.

A noise standard of 55 dB(A)_{L_{Aeq}} (daytime) and 45 dB(A)_{L_{Aeq}} (night time) at locations on the boundary will be used. Monitoring results will be compared against these standards.

Section 40(4)(b) of the Waste Management Act 1996 requires that the activity shall not cause environmental pollution, which as defined as:

"The holding, transport, recovery and disposal of waste in the manner which would to a significant extent endanger human health or harm the environment, and in particular:

- a) Create a risk to waters, the atmosphere, land, soil, plants or animals*
- b) Create a nuisance through noise, odours or litter*
- c) Adversely affect the Countryside or places of special interest".*

Monitoring of groundwater, surface water, noise, visual impact and dust emissions in addition to ecological, archaeological and human receptor surveys have been considered within the scope of this application. No significant environmental impacts were identified, therefore the requirements of Section 40(4)(b) of the Waste Management Act 1996 are deemed to be satisfied.

Section 40(4)(bb) of the Waste Management Act 1996 as amended in 2003 requires the activity to comply with Council Directive 1999/31/EC on the landfill of waste.

The site will be developed and operated in accordance with the requirements of the Landfill Directive.

Section 40(4)(c) of the Waste Management Act, 1996 requires that BATNEEC (Best Available Technique Not Entailing Excessive Costs) principles are implemented to minimise as far as practicable potential emissions from the site.

♣ **Liquid Emissions:** Leachate in the extension to the site will be collected in engineered cells, designed in accordance with the Landfill Directive. Further, with the phased profiling and capping of the existing site, leachate generation will decrease significantly. Assessment has shown no significant impact on major watercourses away from the site and the environmental impact will be reduced progressively as the existing site is restored. The BATNEEC principle for modern landfill sites is generally accepted as being designed, operated and closed in accordance with the Landfill Directive.

♣ **Emissions to Air:** Landfill gases generated within the landfilled cells will be controlled by venting through passive vents. With the phased capping of the site, it is proposed to introduce a landfill gas flare.

Operational procedures such as the spreading, compaction and covering of wastes are also to be implemented to minimise odour and dust emissions from the site in addition to controlling wind blown litter and pests such as flies and vermin.

Section 40(4)(cc) of the Waste Management Act 1996 as amended in 2003 requires the activity to be consistent with the objective of relevant waste management plan, and will not prejudice measures taken or be taken by the relevant local authority or authorities for the purpose of the implementation of any such plan.

The proposed site is consistent with the Donegal Waste Management Plan, which was the subject of widespread public consultation, and adopted by the Council in 2000. This Plan identified the need for an additional 2 - 4 landfill facilities in Donegal, to provide secure long-term disposal for the County.

Section 40(4)(e) of the Waste Management Act, 1996 requires that financial provision are provided for the facility.

Donegal County Council will provide the funding to operate the Landfill Facility in accordance with legislation.

The necessary Personnel will be employed and trained in the appropriate techniques to manage the Landfill in compliance with legislation.

Section 40(4)(f) of the Waste Management Act 1996 as amended in 2003 requires that energy will be used efficiently in the carrying on of the activity concerned.

The environmental management system for the facility will include the provision for the undertaking of an energy audit.

Section 40(4)(g) of the Waste Management Act 1996 as amended in 2003 requires that any noise from the activity will comply with, or will not result in the contravention of any regulation under section 106 of the Act of 1992.

The standards applicable to noise emissions at the site are as follows: BS5228 (1984 and 1987) 'Noise Control on Construction and Open Sites' Part 1.

A noise standard of 55 dB(A) L_{Aeq} (daytime) and 45 dB(A) L_{Aeq} (night time) at locations on the boundary will be used. Monitoring results will be compared against these standards.

Section 40(4)(h) of the Waste Management Act 1996 as amended in 2003 requires that necessary measures will be taken to prevent accidents in the carrying on the activity concerned and, where an accident occurs, to limit its consequences for the environment.

An Environmental Management System will be set up at the facility to include environmental management and operational procedures and emergency response procedures. The local fire authority will be consulted with regards to fire fighting procedures for the facility and onsite equipment required. Fire drills will be undertaken. Site personnel will be trained in first aid and appropriate equipment provided on site. Spill kits will be provided on site. Emergency response procedure will include a management structure for the dealing with all emergencies on site.

Power for the site will be provide

Section 40(4)(i) of the Waste Management Act 1996 as amended in 2003 requires that necessary measures will be taken upon the permanent cessation of the activity concerned of the activity concerned (including such a resulting from the abandonment of the activity) to avoid any risk of the environmental pollution and return the site of the activity to a satisfactory state.

d by an on site generator, with a stand by facility.

The site will be restored in accordance with the requirements of the Landfill Directive. The capping system will include a landfill gas collection layer with a geosynthetic clay liner, a surface water drainage layer and various sub-soil and topsoil finishing layers. The restored site will be subject to an aftercare period involving environmental monitoring, which will continue whilst the waste management licence is maintained.

A.1.11 Environmental Emissions

Environmental emissions anticipated from the proposed Meenaboll Landfill Site are set out below, together with any control measures, which will be undertaken as part of the sites operational procedures.

Leachate: is produced by incident rainfall over the area of the landfill which percolates into the waste pile. A leachate collection system will be constructed. Leachate will be collected and pumped to a treatment tank where it will be subject to pre-treatment prior to disposal to a Sewage Treatment Works or recirculated through the waste to promote more rapid degradation. The leachate from the Meenaboll site will be transported to the Letterkenny Waste Water Treatment Works or to an alternative facility agreed with the EPA.

Landfill gas: the principle constituents of Landfill Gas, which are methane and carbon dioxide, are generated as the putrescible fractions within the landfill degrade. Carbon dioxide levels predominate during the early stage of degradation. The anaerobic stage, in a mature landfill, produces a ratio of methane to carbon dioxide of 2:1. The potential risks associated with these relate primarily to the flammability of methane and the asphyxiant properties of carbon dioxide. Consequently, a landfill gas collection system will be incorporated into the development to provide the necessary control.

The engineered composite lining system proposed for the landfill base and sides, together with the capping system when infilling is completed should provide an adequate barrier to the uncontrolled migration of landfill gas to the atmosphere or surrounding strata. As a result, provision must be made for an active gas extraction system to ensure that gas generated within the landfill mass can be disposed of in a controlled manner.

Dust: is principally generated within landfill sites by vehicles trafficking the access track during dry or windy weather.

Noise: The potential for noise from the proposed development can be split into a number of sections, which are subject to separate noise impact assessments. These sections are landfill operation, vehicle noise and construction noise.

Odours: Donegal County Council have identified that odours can be reduced by good site management and as such ensure that waste is adequately and quickly covered and effectively compacted. Excavation of previously deposited waste is avoided if possible. Donegal County Council will ensure that any complaints are addressed as a matter of priority.

Regular site inspections and monitoring will be carried out in accordance with the EPA licence, and will note any problems arising from landfill operations. The conditions of the licence will include measures to minimise or prevent nuisance to the public occurring as a result of the operation of the facility. A complaints register will detail any complaint received from the general public in respect of the operation of the facility will be maintained at the site.

A.1.12 Assessments of Environmental Impacts

Each potential impact is discussed and details of mitigating measures, designed to minimise any adverse effects, are presented.

Air and Climate

The annual average rainfall for the site is approximately 1600mm. The mean monthly temperature ranges from 4.8°C to 15.0°C. The predominant winds measured are from the south and southwesterly directions.

The aim of this assessment is to estimate the extent of gas emissions that may arise during the operation of the waste management facility and their potential impact on the surrounding environment in terms of lateral migration, atmospheric dispersion and global warming; and to propose appropriate mitigation measures.

The proposed landfill site is located in a rural area with the nearest residential property over 2 Km from the site, therefore no long term sensitive receptors were identified in close proximity of the site. In addition to this, the site will only accept household, commercial, construction and demolition wastes, thereby minimising any potential toxic or hazardous emissions from the site.

In terms of mitigating measures, the impact from gas emissions will be minimised by implementation of measures such as gas venting and flaring while odour will be controlled by rapid deposition and covering of waste, and installation of a capping system and a flaring system. Dust will be minimised by immediate disposal of dusty wastes, damping down materials during very dry weather and a careful choice of daily cover.

Monitoring will be undertaken throughout the life of the landfill site. The following environmental factors (amongst others) will be included in the monitoring programme.

- ♣ Landfill gas
- ♣ Meteorological conditions
- ♣ Odours
- ♣ Dust

In addition, regular site inspections will be carried out, which will note any problems arising from the landfill operations, including the above. The Impact Assessment demonstrated that the development should not have a significant impact on the existing air quality in the surrounding environment.

Flora and Fauna

The habitat in the proposed development site is characterised by conifer plantation forestry, which is highly modified, non-native woodland. Most of the area was clear-felled and replanted with a 2nd rotation within the last ten years. The existing vegetation is transitional and reflects the response of ecological processes to this type of land-use and the changes which have taken place.

Field survey work to collect data on the fauna of the existing environment of the site and surrounding habitats was carried out from September 2002 to July 2003. The field surveys were structured to attain information on wintering birds and other fauna, as well as summer breeding birds and other fauna. The survey area was extended well beyond the proposed development site, to encompass adjacent areas of ecologically important habitat hosting important, sensitive species, which could be considered in the baseline Information and the assessment of impacts.

In spite of the fact that the site and adjoining afforested habitats are highly modified, the composition of plant communities and species still bears a strong resemblance to natural upland habitats, especially within the 2nd rotation forestry where the vegetation has recovered to form a semi-natural groundcover, containing as yet quite a high diversity of species. Plant species diversity would be expected to decrease again within much of the 2nd rotation plantation as the conifer matures to closed-canopy forest. Diversity of fauna species was also found to be moderately high with 27 out of 34 recorded breeding bird species occurring in the four 1km squares dominated by forestry habitats, while 19 of the total were recorded in the four squares dominated by moorland habitats. A total of 49 species were recorded in both winter and summer bird surveys. Mammal species were also quite diverse with Red Deer, Irish Hare and Otter recorded in the survey area.

Given sufficient scope, it is possible that a range of habitat management measures, targeted particularly at the more important and vulnerable bird species recorded in the surveys, could support and conserve these species at a favourable conservation status.

Farm and Animal Health

The site is situated in an area of hill bog land and forestry development and, other than the extensive grazing of small numbers of hill sheep, there is no significant farming activity in the area.

As mentioned previously, the site will be for the acceptance of low risk waste and therefore will contain no high risk condemned, diseased or high-risk biodegradable.

Wind blown debris will be kept to a minimum on site by using netting systems and by placing cover material on the working face of the landfill at the end of each working day. Dust will be controlled by the immediate burial and disposal of dusty wastes. All embankments and stockpiles will be vegetated immediately to reduce the surface area of soil open to the environment.

Roads in the vicinity of the site will be swept on a regular basis and wheelwash facilities will be in place to ensure dust emission on site is not caused from the tyres of vehicles using the landfill site.

The lack of significant farming activity in the area, and the "extensive" nature of hill sheep grazing reduce the likelihood of any individual animal's health being compromised by activities at the landfill to an extremely low level.

Geology and Soils

The geological setting of Meenaboll Landfill site was examined by means of a desk study, walkover survey and an exploratory ground investigation.

The proposed landfill is entirely underlain by metamorphic rocks assigned to the Upper Falcarragh Pelite Formation, a sub-division of the Dalradian Supergroup. The bedrock is completely mantled by a variable thickness drift deposits comprising a lower horizon of boulder clay and an upper peat layer.

No regional faults or slides are shown to pass through the study area. The Knockateen slide as a northeast to southwest trending thrust fault, represents the nearest structural feature to the site. The fault plane is inclined to the southwest beneath the summit of Meenaboll Hill and does not extend beneath the site.

Peaty topsoils mantle the entire site area, which is associated with very poor drainage conditions, where the soils are waterlogged for most of the year. These soil conditions are only suitable for rough grazing purposes, or in the case of the study area coniferous plantation. The textural limitations of the peaty soils also inhibit attempts to improve the drainage of the material.

The development of the landfill site will inevitably lead to the disturbance and/or **loss** of the peaty topsoils over an area of **4.5** hectares. However, the **loss** of these soils would not represent a significant environmental impact as they are of limited agricultural amenity and occur extensively throughout the region.

The construction of the landfill also has the potential to destroy any features of geological interest that may exist within the site. However, no bedrock exposures, drift deposits or landforms of special geological or scientific interest exist within the study area. The construction of the landfill and resultant **loss** of prevailing geological features at the site would not therefore represent a significant environmental impact as high quality exposures occur extensively throughout the region.

To mitigate the construction impacts of the proposed landfill, all mechanically suitable topsoil, subsoil and rock materials will be stockpiled onsite for reuse in earthwork and landscaping operations in each phase of the sites development. The materials will be either reused directly or as soon as possible after their excavation. Proper material handling and storage practices will be adopted to minimise the potential effects of wetting and weathering on the workability and the mechanical properties of the materials. Material stockpiles will be constructed with graded banks to promote surface runoff.

Hydrology

The study area is drained by the Sruhanpollandoo stream, which flows in a northwesterly direction through the site. The stream is a tributary of the Cummirk River and is consequently within the Finn Catchment. The Sruhanpollandoo rises to the east of the site and flows through coniferous forest, hill land and a wooded glen at the downstream section.

Two detailed topographical surveys of the area were undertaken on the site in conjunction with existing maps and a visual inspection of the surface water flows at the site. Based on this information, no surface water originating within the boundary would naturally drain to the Gartan catchment. Indeed the proposed site has been strategically located to ensure that the landfill is not located within Gartan catchment.

An improved surface water management system will be established in the vicinity of the site to minimise the impacts on water quality and quantity in the adjacent watercourses and downstream in the River Finn.

Prior to any construction work commencing on site settlement lagoons and Constructed Wetlands will be developed at the facility. This will assist with ensuring sediment transport off site is minimised. The Sruhanpollandoo stream, which runs adjacent to the landfill area, will be culverted through the site to prevent the possibility of sediment entering the stream.

The ongoing monitoring of surface water quality at the landfill site will be continued, ensuring the effective management of the drainage system.

Hydrogeology

The protection of surface water and groundwater resources is a determining factor in the assessment of the acceptability of a site for landfill development. The potential impact on surface water and groundwater resources generally depends on the prevailing geological and hydrogeological setting of the landfill and the nature and volume of any leachate leakage from the site.

The potential environmental impacts on groundwater and surface waters that may arise from landfilling of wastes principally relate to the generation of leachate within the landfill and its leakage into the environment.

Under current legislation, the primary objective of landfill design is to provide effective control measures to prevent, or reduce as far as possible, leachate emissions from a site. This is necessary in order to ensure potential impacts on the environment are reduced to an acceptable level.

The hydrogeological risk assessment considered the potential impact of the landfill on the groundwater resources. This was based on a conceptual model of the prevailing ground conditions and groundwater flow regime, which were determined by the exploratory investigations and groundwater-monitoring programme.

A principal consideration that controlled the siting of the proposed landfill within the study area was that it should lie outside the Lough Gartan catchment area, which is used as a public water supply. Investigation and modelling of the surface water and groundwater regimes in the area have established that watershed that divides the Finn catchment from the Lough Gartan catchment is located across the slope some 300m beyond the proposed landfill boundary. The investigations demonstrated that the groundwater and surface water that drains through the study area is directed toward the Finn catchment. Therefore there will be no impact on surface water and groundwater abstractions with the Lough Gartan catchment.

Groundwater protection policy for the development of landfills in Ireland is referenced against a Groundwater Protection Matrix that has been developed by the Geological Survey of Ireland (GSI). This provides a determination of the acceptability of the proposed site for development as a landfill, based on the groundwater resource potential of the bedrock and the protection afforded by any overburden deposits.

The Geological Survey of Ireland classifies the metamorphic rock that underlies the site as a poor and generally unproductive aquifer. This rock will directly underlie the landfill, as any overburden cover will be removed during the construction of the landfill cells. These conditions place the proposed landfill site at Meenaboll in the R2¹ response category of the groundwater protection matrix.

In accordance with the groundwater protection matrix response category the proposed landfill development is indicated to be 'Acceptable Subject to Guidance in the EPA Landfill Design Manual or conditions of a waste licence'.

Following the above to assess the significance of the landfills impact on the groundwater resources and examine the effectiveness of the engineered containment system a probabilistic risk assessment was undertaken using LandSim software. This was based on a conceptual model of the site.

The model was developed using parameters representative of the prevailing ground conditions, which were recorded by the exploratory ground investigations. It also simulated the engineered barrier and leachate control systems incorporated in the design of the proposed facility.

The LandSim model calculated that the volume of leachate leakage from the proposed landfill will be minimal following its development as an engineered containment landfill, operated in accordance with current best practices with phased capping and restoration.

The LandSim model also examined the impact key leachate pollution indicators (ammonia, chloride, mercury and potassium) at a groundwater compliance point located 60m downgradient of the proposed Phase I landfill boundary. The results of the analysis determined that no significant contaminant loading on groundwater quality would arise from the leakage from the engineered containment phases.

On the basis of the above the proposed development of the Meenaboll site as a fully engineered containment landfill site would meet the requirements of the EC Landfill Directive and Groundwater Directive with respect to off site compliance.

Human Beings

Human beings form one of the most important aspects of the environment to be considered. This section of the EIS is split into three parts: socio-economic aspects, tourism aspects and human health. The first two parts consider the human environment in the vicinity of the application site in terms of its population profile and trends, labour force profile, socio-economic profile and an assessment of the tourist impacts. The final part considers current available literature for Health Research Board on the health effects of landfills.

The proposed development of a modern landfill has inherent benefits to the socio-economic fabric of the catchment area. It also has a number of beneficial impacts on local sectors of the economy. The tourism sector is an important part of the economy of the northwest. The future development, and indeed expansion of the sector relies on the provision of essential services such as waste disposal. The proposed development is a critical factor in the sustainability of the local tourism sector, as well as other local employment generating industries.

Impact on the Socio-Economic Fabric of the Region

The proposed development of a landfill site in the Meenaboll area of Donegal will impact on the inhabitants of the area. The majority of these impacts will be positive and are detailed below.

During the construction phase of the development employment will be created and sourced from the surrounding area. This will have a positive impact on employment levels in the short term. The proposed landfill will require operatives to collect refuse, transport, compress and oversee the process. The proposed development will therefore sustain current employment levels in the refuse collection/disposal sector but will potentially create additional employment for inhabitants of the area.

The remote nature of the site will ensure that disturbance to inhabitants of the general area is effectively eliminated. The impact on current land uses in the area will be negligible.

Impact on the Tourist Industry

The development of this proposed landfill site will have an imperceptible impact on the number of tourists travelling to the County. The site is not on any recognised tourism routes and therefore its presence will be unknown to visitors unless happened upon by chance. Hence the proposed development will not adversely impact on the established tourism centres of Glenveagh National Park, Letterkenny or Fintown. Indeed the development of the facility is an important factor in ensuring the required waste management infrastructure is available in the mid and West Donegal to allow the tourism industry to develop.

Impact on Human Health

The potential risk to human health from landfill is from the migration of landfill gas and the contamination of surface and groundwater by leachate. A study on the health effects of landfilling was undertaken by Health Research Board (HRB), 2003 at the request of the Department of the Environment Heritage and Local Government. The summary of this report states that studies show an increased risk of some adverse health effects linked to residence near certain specific sites. However, even with a great number of studies, evidence of a causal relationship between specific health outcomes and landfill exposure is still inconclusive.

Landscape and Visual

The site of the proposed landfill facility is located in the Glendowan Mountains, to the north west of Meenaboll Hill and close to the headwaters of the Owenbeg and Sruhanpollidoo Rivers. The site is 11.6km south of Glenveagh Castle, 14km from the Glenveagh National Park Visitor Centre, and 0.5km east of the SAC site Clogheragoare Bog.

Extensive areas of poor quality blanket bog cover much of the area and severely limit agricultural activity, which is more evident in the lower sheltered valleys in the form of dairying and beef production. Open grazing is the main agricultural activity on the bogland.

Extensive areas of conifer forests cover much of the lower slopes and valley sides in the area. These break up the visual character of the area with their dark form and regular outline at variance with the surrounding landscape. There is also evidence of domestic peat cutting in the local area.

Views of the site from the surrounding landscape would be limited to farmers using the hills, forestry workers and occasional hill walkers. The degrees of visual intrusion experienced by these people would depend on the sensitivity of the receptor and a range of factors, including distance from the site, direction of view, local weather conditions etc.

For example in the case of hill walkers, their expectation of views may be considered to be higher and so they may be more sensitive to changes in the visual quality of the area. Effective screening measures and progressive site restoration would be the most effective means of limiting visual intrusion.

Material Assets

A two phased study took place to ascertain the impact of the proposed development on material assets. The first phase comprised a desk study of all available archaeological, historical and cartographic sources. The second phase involved a field inspection of the proposed development area to determine the impact on the market value of the site.

Archaeological Impact

The study found there are no known archaeological sites within the townland of Meenaboll. However due to the size of the proposed development, it is envisaged that deep and extensive machine excavation would be required. This may have a negative impact on any archaeological features and deposits which may remain in the area. In addition to this, the passage of machinery and vehicles may have a negative impact on any previously unrecorded sub-surface remains that may survive within the proposed development.

In order to mitigate against these effects, it is proposed that all groundworks be monitored by an archaeologist to assess the scale of the impact.

Impact on Market Development

Development of a landfill site can potentially result in a perceived negative impact on commercial investment and property values in the area of the site. There are no residential properties on the county road between the R250 and the site. However it is proposed to carry out remedial works along the access route to the site to reduce the impact for local road users.

Studies in relation to the impact of landfills on property prices are not available for the Republic of Ireland or Northern Ireland. However a study to identify and estimate the disamenity costs of landfill in Great Britain was produced by Cambridge Econometrics.

Disamenity costs are the local nuisance impacts caused by landfill activity and experienced by households living close to landfill. The local nuisance impacts include odour, dust, litter, noise, vermin and visual intrusion. The report indicates the property values reductions vary dependent upon distance from the landfill but no evidence of reduction was reported at distances greater than ½ mile from the sites.

Noise

The site is surrounded by hills and therefore hidden from view from road traffic and is located more than 2Km from the nearest residential property. The land is currently in use by the forestry service.

The potential for noise from the proposed development can be split into a number of sections, which are subject to separate noise impact assessment. These sections are landfill operation, vehicle noise and construction noise.

Landfill Operation

The noise assessment has shown that the potential noise impact from activities, at the most proximate residential properties, is below daytime target levels while the operation of the leachate treatment system and the flare unit together will not exceed night time limits.

As part of the site preparation works including, removal of overfill, it is proposed to use the surplus material to create earth bunds. These have the dual benefit of acting as visual screening barriers and acoustic barriers.

Vehicle Noise

This assesses the impact of traffic movement on roads approaching and within the boundaries of the site including the impact of service vehicles.

It is predicted that the potential noise impact from 'worst case' HGV activity on the site roads will be within the day target level at the most proximate residential property. Based in the information provided in the TIA, worst-case increase noise levels due to transportation on the local supply roads will be imperceptible.

Construction Noise

This assessment is based on guidelines and recommendations from the relevant British Standard dealing with construction noise as presently there are no fixed noise levels for construction noise in Ireland and the control of such sources is outside the remit of the EPA.

In order to mitigate the impact from construction noise, it is recommended that contractors apply appropriate measures where practicable, including temporary screening or enclosure of noisy plant, control of on times for noisy plant and positioning of plant.

Transportation

The existing road leading to the site is currently unused apart from Glenveagh Nation Park and logging traffic. The Connecting R250 links traffic from Letterkenny to Fintown and other local towns and villages in northwest Donegal.

Traffic generations from the proposed development of Meenaboll Landfill have been calculated by counting and analysing the daily flow of existing traffic at Ballynacarrick Landfill, including development traffic to the site to predict peak hour traffic flows. This has included a classified traffic count at the existing access and the adjacent priority junction to the south of the site access.

The proposal includes resurfacing access roads and generally improving road conditions. This will include the provision of lay-bys at identified points to ensure there is no conflict between vehicles entering and leaving the site.

Overall it can be concluded that the impact of the traffic to and from the site will not have a significant impact on the surrounding road network, and with minor improvements, there will be no net detriment on the surrounding road network as a result of this proposal.

A.1.13 Monitoring and Sampling Arrangements

Proposed monitoring stations for leachate, groundwater, surface water, landfill gas and dust have been identified. Monitoring at these locations will be undertaken in accordance with the guidelines set out in the Environmental Protection Agency, Manual on Landfill Monitoring. All monitoring data will be assessed by a nominated competent person within Donegal County Council, who sanctions appropriate measures to mitigate any problems identified.

A.1.14 Prevention, Minimisation and Recovery of Waste

The Donegal Waste Management Plan will be reviewed in February 2005; however the following treatment of waste is being undertaken in the County:

Bring Bank Centres

There are currently 55 bring bank centres throughout the County and additional sites are being sourced. At these centres the council provides bring banks for beverage cans, brown/green/clear glass and textiles. Recycling services to include paper, card and plastics have been introduced to selected sites throughout the County.

Civic Amenity Sites

Donegal County Council has one Civic Amenity Site in operation in Carndonagh. This site offers recycling outlets for metals, electrical goods, wooden goods, batteries, oil, fridges, glass, cans and textiles.

Construction of a Civic Amenity Site at Stranorlar will commence in 2005. Other sites are currently being assessed in Letterkenny and Laghey. The Council are currently seeking sites in the Milford and Glenties Electoral area. These Civic Amenity facilities will deal with household hazardous waste.

Currently the Chemcar is hired to deal with household hazardous waste in areas without a Civic Amenity facility.

Recycling facilities have also been included in the proposed landfill project at the Meenaboll site.

Composting

Donegal County Council has subsidised the provision of some 5,000 home composting bins throughout the County.

Further treatment of biodegradable waste streams will be reviewed as part of the Waste Management Plan review in February 2005.

Battery Recycling Bins

Battery recycling bins have recently been located at six Super Valu Supermarkets in Donegal. Domestic batteries can now be recycled in these outlets in Raphoe, Carndonagh, Letterkenny, Donegal Town, Dungloe and Ballybofey.

Kerb Side Collections

A number of kerb side collections commenced in 2004. It is expected that a greater coverage of kerbside collection from households will be undertaken in 2005 as part of the current review of waste collection permits by Donegal County Council.

A.1.15 Off Site Treatment or Disposal of Solid or Liquid Wastes

A leachate collection system will be installed within the landfill development. Leachate will be collected and pumped to a treatment tank where it will be subject to pre-treatment prior to disposal to a Sewage Treatment Works or recirculated through the waste to promote more rapid degradation. The leachate from the Meenaboll site will be transported to the Letterkenny Waste Water Treatment Works or to an alternative facility agreed with the EPA.

A.1.16 Emergency Procedures

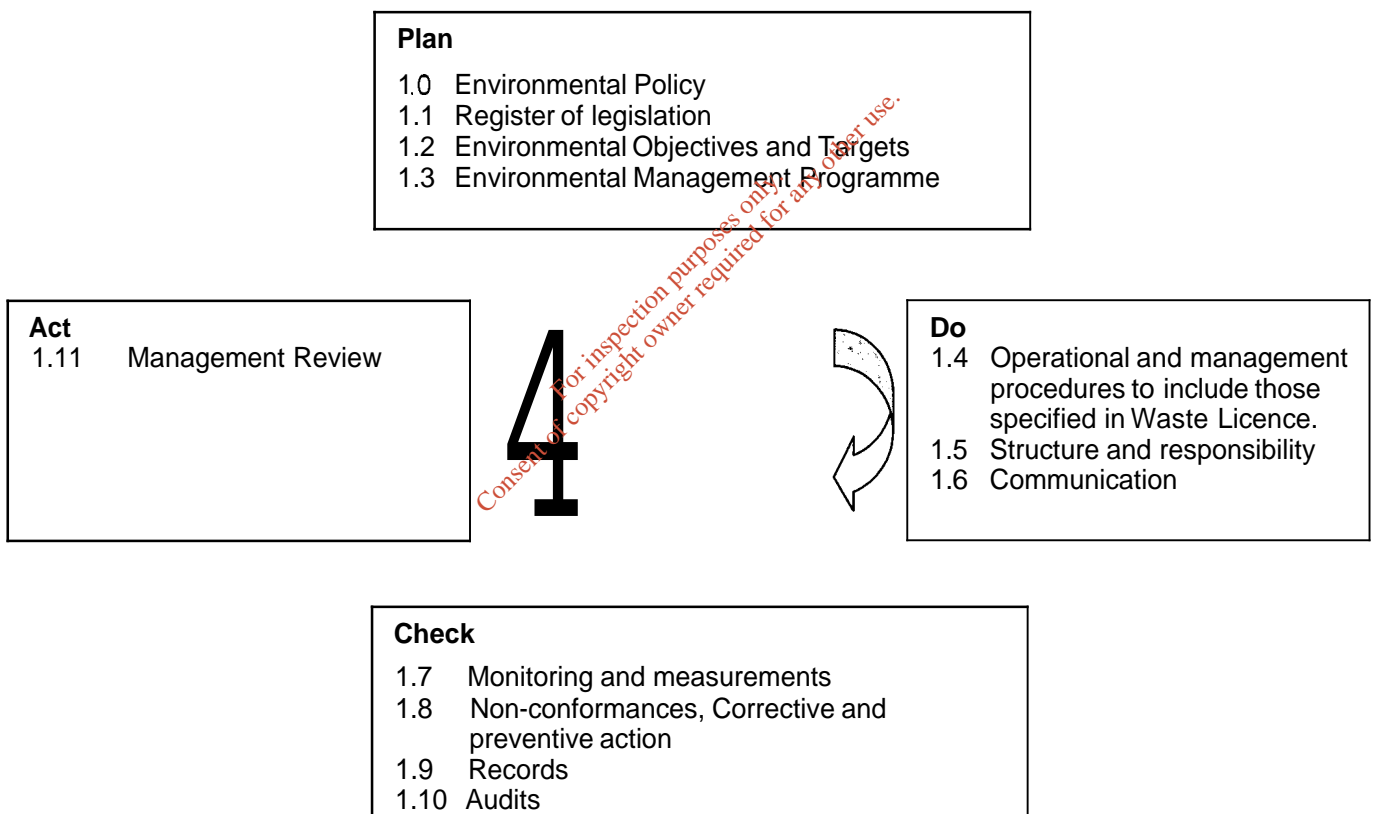

An Environmental Management System will be developed for the facility, which involves the implementation of a system, which forms the basis of continuous, structured and quantifiable improvement in environmental performance. The EMS for Meenaboll Landfill Site will become part of the overall management system for the site, and will deal with the environmental issues relating to the facility and control potential environmental impacts. Environmental and operational procedures will be drawn up for all site activities. Computerised controlling system will be installed for leachate and landfill gas management at the facility.

Emergency situations will be handled initially by the staff on site who will inform the necessary emergency services or departments within Donegal County Council. The following measures will be undertaken:

- ♣ Site safety procedures will be adopted on site.
- ♣ Trained first aider available on site.
- ♣ First aid kit available on site.
- ♣ Emergency procedures and emergency numbers displayed on site buildings.

All emergency situations will be reported immediately to the Senior Executive Engineer. Procedures will be reviewed following any incident.

The EMS will be based around the following concept of continuous improvement.

A.1.17 Closure Restoration and Aftercare

A key component of landfill design is the restoration and aftercare of the landfill after it has ceased receiving wastes. The purpose of this process is to cap the site to reduce leachate generation, to facilitate environmental management and to return the landscape to beneficial use.

Following completion of infilling and allowing time for settlement, groups of cells will be capped and progressively restored. Once any one phase has been capped, it will be restored in the first available soil moving season. The final contours will be designed to enable the implementation of the intended after use and to blend into the surrounding landscape.

The capping system will include a landfill gas collection layer with a geosynthetic clay liner, a surface water drainage layer and various sub-soil and topsoil finishing layers. Additional depths of soil will be provided in the areas where tree planting is proposed over the landfill cap.

In terms of landscaping, it is not proposed to carry out major areas of landscaping on the landfill site itself. This is consistent with good landfill practice, as root systems from trees and shrubs may adversely affect the capping system. However, it is recognised that the restoration of the site would benefit from the planting of hedgerows and trees both in terms of creating a visually acceptable landscape in the long term and help, where possible, to screen operations by advance works.

It is envisaged that an aftercare programme will be drawn up prior to the completion of each phase of the landfill. Each restored cell will be subject to an initial aftercare period. During this period, an annual inspection will take place and this will be over and above the environmental monitoring, which will continue whilst the waste management licence is maintained.

A.1.18 Financial Arrangements

Donegal County Council is a local authority and is committed to the provision for the management, development and restoration of Meenaboll landfill site.

A.1.19 Seveso II

S1 No 476 of 2000 does not apply to the proposed development at Meenaboll.

A.1.20 Council Directive 80/68/EEC

The landfill will comply with the Directive.
