## Executive Summary

Odour Monitoring Ireland Ltd was commissioned by Panther Environmental Ltd. to perform a desktop odour and NH<sub>3</sub> dispersion modelling assessment of library odour and NH<sub>3</sub> emissions from a proposed expansion to a pig production facility located in Woodville, Ballymackey, Nenagh, Co. Tipperary. The operation of the proposed pig production facility will lead to emissions of Odours and Ammonia and by using atmospheric dispersion modelling, the potential impact of these pollutants were assessed and compared to relevant ambient guideline odour and Ammonia limit values including the methodology contained within the Irish EPA publication "Odour impacts and odour emissions controls for Intensive Agricultural Facilities", AG4 - Air Dispersion Modelling from Industrial Installations Guidance Note and "Odour Management at Intensive Livestock Installations" published by the Environment Agency UK May 2005. These documents lay out general methodologies for assessing the risks of odours and gaseous pollutants from such sites on a conservative basis.

Odour emissions rates, limits and dispersion modelling guidance were taken from reference data including:

1. "Odour Impacts and Odour Emission Control Measures for Intensive Agriculture" Final Report Environmental Research R&D Report Series No. 14 published by the Irish Environmental Protection Agency 2006,
2. "Odour Management at Intensive Livestock Installations" published by the Environment Agency UK May 2005,
3. "Air Dispersion Modelling from Industrial Installations Guidance Note (AG4)" published by the Irish Environmental Protection Agency 2010.
4. Van Geel, P.L.B.A. (2006) Annex 1 - Odour nuisance and farming act, Netherlands.
5. Sniffer ER26 Final Report, March 2014.
6. [http://www.environment-agency.gov.uk/static/documents/Utility/modelling\\_2104566.pdf](http://www.environment-agency.gov.uk/static/documents/Utility/modelling_2104566.pdf)
7. [http://www.environment-agency.gov.uk/static/documents/BusinessGuidance\\_on\\_modelling\\_of\\_ammonia\\_from\\_poultry\\_pig\\_farms.pdf](http://www.environment-agency.gov.uk/static/documents/BusinessGuidance_on_modelling_of_ammonia_from_poultry_pig_farms.pdf)

Odour and NH<sub>3</sub> emission data sets were calculated to determine the potential impact of the existing and proposed pig production facility during its expected operation. The odour and NH<sub>3</sub> emission data set was taken from published sources to include "Odour Impacts and Odour Emission Control Measures for Intensive Agriculture" Final Report Environmental Research R&D Report Series No. 14 published by the Irish Environmental Protection Agency 2006, Van Geel, P.L.B.A. (2006) Annex 1 - Odour nuisance and farming act, Netherlands and Sniffer ER26 Final Report, March 2014 and Sniffer ER26 Final Report, March 2014.

The dispersion modelling scenarios assessed included:

- Ref Scenario 1:** Predicted overall Odour emission rate from the existing pig production facility operations (*see Table 3.1*).
- Ref Scenario 2:** Predicted overall Odour emission rate from the proposed pig production facility operations (*see Table 3.2*).
- Ref Scenario 3:** Predicted overall Ammonia emission rate from the existing pig production facility operations (*see Table 3.3*).
- Ref Scenario 4:** Predicted overall Ammonia emission rate from the proposed pig production facility operations (*see Table 3.4*).

Average modelling scenarios were performed to allow for comparison with relevant odour and Ammonia impact criteria as described in *Section 2.6*. These included 1-hour mean, Annual average and maximum number of exceedances expressed as percentiles (i.e. 98<sup>th</sup>). All processes and source characteristics as outlined within the emission tables were used in conjunction with library air emissions data to construct the basis of the dispersion model. Five

years of hourly sequential meteorological data (Shannon Airport 2016 to 2020 inclusive) was screened to ascertain the worst case year. Shannon Airport 2017 was determined as worst case dispersion year used within the dispersion model in order to provide statistical significant conservative ground level concentration estimates over each of the screened five years. Shannon Airport met station was chosen as it is located approximately within 50 km from the existing operating farm (as the crow flies).

Aermod Prime (21112) was used to determine the overall odour impact of the existing and proposed pig production facility operation located in Ballymackey, Nenagh, Co. Tipperary. In terms of prediction of overall odour and Ammonia impact area, the following contour plots were examined and presented as a worst case scenario.

These included:

**Ref Scenario 1 – Existing Odour impact (excluding background).**

- Predicted odour emission contribution of overall existing pig production facility operation (see Table 3.1), to odour plume dispersal at the 98<sup>th</sup> percentile for an odour concentration of less than or equal to 6.0 Ou<sub>E</sub>/m<sup>3</sup> for worst case year 2017 (see Figure 7.2).

**Ref Scenario 2 – Proposed Odour impact (excluding background).**

- Predicted odour emission contribution of overall proposed pig production facility operation (see Table 3.2), to odour plume dispersal at the 98<sup>th</sup> percentile for an odour concentration of less than or equal to 3.0 Ou<sub>E</sub>/m<sup>3</sup> for worst case year 2017 (see Figure 7.3).

**Ref Scenario 3A & 3B – Existing Ammonia impact (excluding background).**

**Scenario 3A**

- Predicted Ammonia emission contribution of overall existing pig production facility operation (see Table 3.3), to Ammonia plume dispersal at the 100<sup>th</sup> percentile 1 hr average for an Ammonia concentration of less than or equal to 50 µg/m<sup>3</sup> for worst case year 2017 (see Figure 7.4).

**Scenario 3B**

- Predicted Ammonia emission contribution of overall existing pig production facility operation (see Table 3.3), to Ammonia plume dispersal as an Annual average for an Ammonia concentration of less than or equal to 3.0 µg/m<sup>3</sup> for worst case year 2017 (see Figure 7.5).

**Ref Scenario 4A & 4B – Proposed Ammonia impact (excluding background).**

**Scenario 4A**

- Predicted Ammonia emission contribution of overall proposed pig production facility operation (see Table 3.4), to Ammonia plume dispersal at the 100<sup>th</sup> percentile 1 hr average for an Ammonia concentration of less than or equal to 275 µg/m<sup>3</sup> for worst case year 2017 (see Figure 7.6).

**Scenario 4B**

- Predicted Ammonia emission contribution of overall proposed pig production facility operation (see Table 3.4), to Ammonia plume dispersal as an Annual average for an Ammonia concentration of less than or equal to 6.0 µg/m<sup>3</sup> for worst case year 2017 (see Figure 7.7).

The results of this examination are presented in Section 4 of this report.

The following conclusions were drawn from the dispersion modelling assessment: Greater detail can be found within the document and it is recommended that the document be read in full. The main conclusions include:

- Dispersion modelling of Odour and Ammonia emissions from the existing and proposed pig production facility was performed in accordance with AG4 and best international practice with a minimum of five years of hourly sequential meteorological data used in the dispersion modelling assessment. Topographical data from Ordnance Survey Ireland was also inputted into the dispersion model in order to take account of the terrain effects in the vicinity of the site. In addition, sensitive receptors were included within the dispersion model in order to predict the level of pollutants at their specific location.
- Worst case referenced library odour and NH<sub>3</sub> emission data was utilised to develop the odour and NH<sub>3</sub> emission dataset for the existing and proposed facility. This was to remain conservative within the assessment.
- With regards to the existing pig production facility operations, the odour plume spread is approximately 150 to 200 m from the facility buildings (*see Figure 7.2*). The maximum predicted ground level concentration of odour at the worst case sensitive receptor in the vicinity of the facility was less than or equal to 0.79 Ou<sub>E</sub>/m<sup>3</sup> for the 98<sup>th</sup> percentile of hourly averages for the worst case meteorological year (*see Table 4.1*). This is less than the guideline odour limit value of less than or equal to 6.0 Ou<sub>E</sub>/m<sup>3</sup> for the 98<sup>th</sup> percentile of hourly averages (*see Table 4.1 and Figure 7.2*).
- With regards to the proposed pig production facility operations, the odour plume spread is approximately 1,300 m from the facility buildings in a north westerly and north easterly direction (*see Figure 7.3*). The maximum predicted ground level concentration of odour at the worst case sensitive receptor in the vicinity of the facility was less than or equal to 2.64 Ou<sub>E</sub>/m<sup>3</sup> for the 98<sup>th</sup> percentile of hourly averages for the worst case meteorological year (*see Table 4.1*). This is less than the guideline odour limit value of less than or equal to 6.0 Ou<sub>E</sub>/m<sup>3</sup> for the 98<sup>th</sup> percentile of hourly averages (*see Table 4.1 and Figure 7.3*).
- With regards to the existing pig production facility operations, the Ammonia plume spread for the 100<sup>th</sup> percentile 1 hour maximum ground level concentration is approximately 150 to 200 m from the facility buildings (*see Figure 7.4*). The maximum predicted ground level concentration of Ammonia at the worst case sensitive receptor in the vicinity of the facility was less than or equal to 31.42 µg/m<sup>3</sup> for the 100<sup>th</sup> percentile of hourly averages for the worst case meteorological year (*see Table 4.2*). This is less than the guideline Ammonia limit value for the protection of human health (*see Table 4.2 and Figure 7.4*).
- With regards to the existing pig production facility operations, the Ammonia plume spread for the Annual average ground level concentration is approximately 100 m from the facility buildings. The maximum predicted ground level concentration of Ammonia at the worst case sensitive receptor in the vicinity of the facility was less than or equal to 0.51 µg/m<sup>3</sup> for the Annual averages for the worst case meteorological year 2017 (*see Table 4.2*). The maximum predicted ground level concentration at the identified Natura sites is less than 0.014 µg/m<sup>3</sup>. This is less than the guideline Ammonia limit value for the protection of ecosystems at these locations (*see Table 4.2 and Figure 7.5*).
- With regards to the proposed pig production facility operations, the Ammonia plume spread for the 100<sup>th</sup> percentile 1 hour maximum ground level concentration is approximately 300 m from the facility buildings in a north easterly direction. The maximum predicted ground level concentration of Ammonia at the worst case sensitive receptor in the vicinity of the facility was less than or equal to 66.95 µg/m<sup>3</sup> for the 100<sup>th</sup> percentile of hourly averages for the worst case meteorological year (*see*

*Table 4.2*). This is less than the guideline Ammonia limit value for the protection of human health (see *Table 4.2 and Figure 7.6*).

- With regards to the proposed pig production facility operations, the Ammonia plume spread for the Annual average ground level concentration is approximately 200 to 250 m from the facility buildings in a north westerly and north easterly direction. The maximum predicted ground level concentration of Ammonia at the worst case sensitive receptor in the vicinity of the facility was less than or equal to  $3.0 \mu\text{g}/\text{m}^3$  for the Annual averages for the worst case meteorological year 2017 (see *Table 4.2*). The maximum predicted ground level concentration at the identified Natura sites is less than or equal to  $0.04 \mu\text{g}/\text{m}^3$ . This is 4% of the Critical exposure limit value of  $1 \mu\text{g}/\text{m}^3$  for Ammonia for the protection of sensitive ecosystems at these locations (see *Table 4.2 and Figure 7.7*).
- With regards to the proposed facility operations, the facility operations will be in compliance with the guideline Odour and Ammonia impact presented within the document.

# 1. Introduction and scope

## 1.1 Introduction

Odour Monitoring Ireland Ltd was commissioned by Panther Environmental Ltd. to perform a predictive odour and Ammonia impact assessment of an existing and proposed extension to pig production facility utilising library emission data and dispersion-modelling software Aermid Prime (21112). Like the majority of industries, the operation of the pig farm is faced with the issue of preventing odours and Ammonia impact to the public at large.

Library based odour and Ammonia emission rates were gathered from reference publications taking into account the current pig housing system in place at the facility. Odour and Ammonia emission scenarios were developed to take account of the existing and proposed design operations. These odour and Ammonia emission rates and specified source characteristics were inputted into Aermid Prime (21112) in order to determine the impact from the existing and proposed facility operations on the surrounding area.

This document presents the materials and methods, results and discussion and conclusions of the desktop examination of potential odours and Ammonia from the facility.

## 1.2 Scope of the study

The main objective of the odour and Ammonia impact assessment is to ascertain whether the levels of emissions from the proposed pig production facility will result in ground level impact in the vicinity of the site operations. Ground level impact refers to the impact at ground level (i.e. normal breathing height of 1.8 m) in excess of the odour and Ammonia impact criteria contained in *Section 2.6* of this document.

The following assessment will take account of the likely and potential impacts associated with the proposed operation of the pig production facility.

The methodology adapted involved a number of distinct steps. These included:

- Calculation of odour and Ammonia emission rates from library based data;
- Prediction of ground level concentrations (GLC's) of compounds dispersed from the emission point source located within the farm;
- Dispersion modelling was carried in accordance with "Air Dispersion Modelling from Industrial Installations Guidance Note (AG4)" published by the Irish Environmental Protection Agency 2010.

## 1.3 Model assumptions

The approach adopted in this assessment is considered a standard investigation in respect of emissions to the atmosphere from a facility.

These assumptions used within the dispersion modelling assessment include:

- Emissions to the atmosphere from the named emission point operations were assumed to occur 24 hours each day over a standard year for all sources.
- Five years of hourly sequential meteorological data from Shannon Airport 2016 to 2020 inclusive was used in the modelling screen which will provide statistical significant results in terms of the short and long term assessment. The worst case year for Shannon Airport met station was 2017 and was used for contour plot and odour/Ammonia data presentation. The predicted odour and Ammonia value at the residential receptors is presented for this year. This is in keeping with current national and international recommendations (EPA Guidance AG4 and EA Guidance H4). In addition, AERMOD incorporates a meteorological pre-processor AERMET PRO. The AERMET PRO meteorological preprocessor requires the input of surface

characteristics, including surface roughness ( $z_0$ ), Bowen Ratio and Albedo by sector and season, as well as hourly observations of wind speed, wind direction, cloud cover, and temperature. The values of Albedo, Bowen Ratio and surface roughness depend on land-use type (e.g., urban, cultivated land etc) and vary with seasons and wind direction. The assessment of appropriate land-use type was carried out to a distance of 10km from the meteorological station for Bowen Ratio and Albedo and to a distance of 1km for surface roughness in line with USEPA recommendations.

- AERMOD Prime (21112) dispersion modelling was utilised throughout the assessment in order to provide the most reliable dispersion estimates.
- All building wake affects on all applicable emission points were assessed within the dispersion model using the building prime algorithm contained within AERMOD Prime (e.g. all buildings / structures were included within the model assessment).
- All receptors were established at normal breathing height of 1.80 above ground level.
- 10 m spaced terrain data was inputted into the model which was taken from Ordnance Survey Ireland.
- Forty seven nearest sensitive receptors including their relative height were inputted into the model in order to assess the level of impact at each receptor location.
- Five natura (NHA, SAC, etc.) sites were included as sensitive receptors within the model in order to assess the predicted levels of Ammonia at these sites.

## 2. Materials and methods

This section will describe the materials and methods used within the study.

### 2.1 Odour and Ammonia emission rate values

Table 2.1 illustrates the odour emission rate figures gathered from a review of EPA Research Report Series No. 14 and Sniffer ER26 Final Report, March 2014.

These specific odour emission rates were utilised in the dispersion model to assess the odour impact of the existing and proposed pig production facility on the surrounding area.

**Table 2.1.** Odour emission rates for specific pig type at the existing and proposed facility.

Pig type	Odour emission factor ( $O_{uE}$ /pig/s)
Sows and piglets	19
Loose sows	19
Farrowing	20
Gilts	20
Weaners	6
Production pigs >30 kgs	22.50

Table 2.2 illustrates the Ammonia emission rate figures gathered from Sniffer ER26 Report. These specific Ammonia emission rates were utilised in the dispersion model to assess the Ammonia impact of the existing and proposed pig production facility on the surrounding area.

**Table 2.2.** Ammonia emission rates for specific pig type at the existing and proposed facility.

Pig type	Ammonia emission factor ( $\mu\text{g/pig/s}$ )
Sows and piglets	185.20
Loose sows	95.45
Farrowing	95.45
Gilts	95.45
Weaners	9.20
Production pigs >30 kgs – No mitigation	98.61
Weaners – FSF with frequent slurry removal	6.98
Production pigs >30 kgs – FSF with frequent slurry removal	37.73

All this information is available from and Environmental Protection Agency report entitled "Odour Impacts and Odour Emission Control Measures for Intensive Agriculture" Final Report EPA 2001. In addition, other relevant publications such as "Odour Management at Intensive Livestock Installations" published by the Environment Agency UK May 2005 and Van Geel, P.L.B.A. (2006) Annex 1 - Odour nuisance and farming act, Netherlands and Sniffer ER26 Final Report were consulted.

### 2.2 Volumetric flow rate values

The volumetric airflow rate values were calculated from fan capacities installed on each pig house on site. This was coupled with diameters and numbers of each emission point in order to calculate efflux velocities from each vent. These are included in Tables 3.2, 3.3, 3.4 and 3.5.

### 2.3 Atmospheric dispersion modelling of air quality: What is dispersion modelling?

Any material discharged into the atmosphere is carried along by the wind and diluted by wind turbulence, which is always present in the atmosphere. This process has the effect of producing a plume of air that is roughly cone shaped with the apex towards the source and

can be mathematically described by the Gaussian equation. Atmospheric dispersion modelling has been applied to the assessment and control of emissions for many years, originally using Gaussian form ISCST 3 and more recently utilising advanced boundary-layer physics models such as ADMS and AERMOD (Keddie et al. 1992). Once the compound emission rate from the source is known, ( $\text{g s}^{-1}$ ), the impact on the vicinity can be estimated. These models can effectively be used in three different ways: firstly, to assess the dispersion of compounds; secondly, in a “reverse” mode, to estimate the maximum compound emissions which can be permitted from a site in order to prevent air quality impact occurring; and thirdly, to determine which process is contributing greatest to the compound impact and estimate the amount of required abatement to reduce this impact within acceptable levels (McIntyre et al. 2000). In this latter mode, models have been employed for imposing emission limits on industrial processes, control systems and proposed facilities and processes (Sheridan et al., 2002).

#### 2.4 Atmospheric dispersion modelling of air quality: dispersion model selection

The model chosen in this study was AERMOD Prime (EPA Version 21112). The AERMOD model was developed through a formal collaboration between the American Meteorological Society (AMS) and U.S. Environmental Protection Agency (U.S. EPA). AERMOD is a Gaussian plume model and replaced the ISC3 model in demonstrating compliance with the National Ambient Air Quality Standards (Porter et al., 2003). AERMIC (USEPA and AMS working group) is emphasizing development of a platform that includes air turbulence structure, scaling, and concepts; treatment of both surface and elevated sources; and simple and complex terrain. The modelling platform system has three main components: AERMOD, which is the air dispersion model; AERMET, a meteorological data pre-processor; and AERMAP, a terrain data pre-processor (Cora and Hung, 2003).

AERMOD is a Gaussian steady-state model which was developed with the main intention of superseding ISCST3 (NZME, 2002). The AERMOD modeling system is a significant departure from ISCST3 in that it is based on a theoretical understanding of the atmosphere rather than depend on empirical derived values. The dispersion environment is characterized by turbulence theory that defines convective (daytime) and stable (nocturnal) boundary layers instead of the stability categories in ISCST3. Dispersion coefficients derived from turbulence theories are not based on sampling data or a specific averaging period. AERMOD was especially designed to support the U.S. EPA's regulatory modeling programs (Porter et al., 2003).

Special features of AERMOD include its ability to treat the vertical in-homogeneity of the planetary boundary layer, special treatment of surface releases, irregularly-shaped area sources, a three plume model for the convective boundary layer, limitation of vertical mixing in the stable boundary layer, and fixing the reflecting surface at the stack base (Curran et al., 2006). A treatment of dispersion in the presence of intermediate and complex terrain is used that improves on that currently in use in ISCST3 and other models, yet without the complexity of the Complex Terrain Dispersion Model-Plus (CTDMPLUS) (Diosey et al., 2002). Additional utilities associated with the dispersion model allow computation of ground level concentrations of pollutants over defined statistical averaging periods, consideration of building wake/downwash effects in the vicinity of the assessed facility.

#### 2.5 Odour and Ammonia impact assessment criteria

Currently, there is no general statutory odour standard in Ireland relating to industrial installations. The EPA has issued guidance specific to intensive agriculture which has outlined:

- The limit of less than  $6.0 \text{ Ou}_E/\text{m}^3$  at the 98<sup>th</sup> percentile of hourly averages should be utilised to provide a minimum level of protection against odour annoyance from Existing Pig Facilities as stated in "Odour Impacts and Odour Emission Control Measures for Intensive Agriculture" Final Report Environmental Research R&D Report Series No. 14 published by the Irish Environmental Protection Agency 2006.

- The limit of less than 3.0  $\text{Oue}/\text{m}^3$  at the 98<sup>th</sup> percentile of hourly averages should be utilised to provide a minimum level of protection against odour annoyance from Proposed Pig Facilities as stated in "Odour Impacts and Odour Emission Control Measures for Intensive Agriculture" Final Report Environmental Research R&D Report Series No. 14 published by the Irish Environmental Protection Agency 2006.
- The indicative exposure level criterion for new facilities, which equates to 'no pollution', i.e. no reasonable cause for annoyance is 3.0  $\text{Oue}/\text{m}^3$  at the 98<sup>th</sup> percentile of hourly averages at sensitive receptors as stated in "Odour Management at Intensive Livestock Installations" published by the Environment Agency UK May 2005.

The predicted odour impact from the operation of the pig farm is compared to relevant odour impact criteria. The relevant odour impact criteria are presented in *Table 2.1*.

With regards to Ammonia impact assessment, the output from the dispersion model will be assessed against the following:

- The limit value of less than 3,300  $\mu\text{g}/\text{m}^3$  at the 100<sup>th</sup> percentile of hourly averages should be utilised to provide protection against Ammonia impact at residential receptors.
- The limit value of less than 1 and 3  $\mu\text{g}/\text{m}^3$  for an Annual average should be utilised to provide protection against Ammonia impact at natura sites.
- If the baseline of pollutant is in excess of the Critical level at the habitat, the limit value reverts to a process contribution of no greater than 4% of the Critical limit value. In this case this can be defined as less than 0.040  $\mu\text{g}/\text{m}^3$ .

## 2.6 Odour and Ammonia Impact Criteria Guidelines in Ireland and the UK

Table 2.1 illustrates the limit values for odour and NH<sub>3</sub> impact assessments in Ireland.

**Table 2.1.** Limit odour impact criteria for pig production facilities in Ireland and the UK.

POLLUTANT	Objective			Measured as	TO BE ACHIEVED BY	VALUE TYPE
	Concentration	Maximum No. Of exceedences allowed	Exceedence expressed as percentile			
Odours <sup>1</sup>	less than or equal to 6.0 O <sub>uE</sub> /m <sup>3</sup>	175 times in a year	98 <sup>th</sup> percentile	1 hour mean	Existing installation	Limit Value
Odours <sup>1,2</sup>	less than or equal to 3.0 O <sub>uE</sub> /m <sup>3</sup>	175 times in a year	98 <sup>th</sup> percentile	1 hour mean	New installation	Limit Value
Ammonia <sup>3,4</sup>	3,300 µg m <sup>-3</sup> NH <sub>3</sub> <sup>3</sup>	Protection of human health	100 <sup>th</sup> percentile	1 hour mean	--	Limit value
	3 µg m <sup>-3</sup> NH <sub>3</sub>	Critical level – Higher plants <sup>4</sup>		Annual mean		
	1 µg m <sup>-3</sup> NH <sub>3</sub>	Critical level – sensitive plants <sup>4</sup>	--	Annual mean		
	<0.04 µg m <sup>-3</sup> NH <sub>3</sub>	Process contribution limit value if Critical level for sensitive plants is exceeded	--	Annual mean		

**Notes:** <sup>1</sup> denotes – Values taken from "Odour Impacts and Odour Emission Control Measures for Intensive Agriculture" Final Report Environmental Research R&D Report Series No. 14. Pg 47 and "Air Dispersion Modelling from Industrial Installations Guidance Note (AG4)" published by the Irish Environmental Protection Agency 2010. Pg 68.

<sup>2</sup>"Odour Management at Intensive Livestock Installations" published by the Environment Agency UK May 2005. Pg. 5

<sup>3</sup> denotes EPR H1 (2008) – Environmental Risk Assessment Part 1 – Simple assessment of environmental risk for accidents, odour, noise and fugitive emissions and EPR H1 (2008) - Environmental Risk Assessment Part 2 – Assessment of point source release and cost benefit analysis.

<sup>4</sup> denotes limit value for the protection of vegetation/ecosystem.

<sup>5</sup> denotes that if critical exposure level for Sensitive plants exceeded, an allowance of 4% of the Critical exposure level is established as process contribution limit value. This would be equivalent to  $0.04 \mu\text{g}/\text{m}^3$ .

## 2.7 Meteorological data

Five years of hourly sequential meteorological data was chosen for the modelling exercise (i.e. Shannon Airport 2016 to 2020 inclusive). Shannon Airport was chosen as the representative meteorological station due to its proximity to the site relative to other synoptic meteorological stations (i.e. located approx. 45 km from the site operations as the crow flies) and based on the fact that it has all the relevant cloud cover data in line with USEPA requirements.

A schematic windrose and tabular cumulative wind speed and directions of all five years are presented in *Section 8*.

## 2.8 Terrain data

Due to the fact that the proposed pig facility is located in complex terrain (based on the fact that low stack based emission points are present within the modelling scenario and relative receptor heights are higher relative to stack height) a terrain file was included in the dispersion modelling assessment. A 10 metre Cartesian grid spaced topographical data was obtained from Ordnance survey Ireland and used to create a 10 metre Cartesian grid \*.DEM file for use in Aermap software within AERMOD Prime.

## 2.9 Building wake effects

Building wake effects are accounted for in modelling scenarios (i.e. all building features located within the pig farm) as this can have a significant effect on the compound plume dispersion at short distances and can significantly increase GLC's in close proximity to the facility. This is particularly important due to the significant changes in elevation around the facility.

### **3. Results-Emission calculations.**

The results of predictive estimation of emissions of Odour and Ammonia from the existing and proposed pig production facility are presented in *Tables 3.1 to 3.4*.

#### **3.1 Predicted Odour mass emission rate from the existing and proposed Pig Production facility**

*Tables 3.1 and 3.2* present the predicted overall odour emission rates for the existing and proposed pig facility operations. Odour emission rate values were gathered from available suitable literature (see *Section 2.1*).

For inspection purposes only.  
Consent of copyright owner required for any other use.

**Table 3.1.** Predicted mass emission value results for odour for existing pig production facility operations.

### 3.3. Dispersion model input data – Source characteristics

Tables 3.1 to 3.4 illustrate the source characteristics utilised within the dispersion model. Stack height (A.G.L), number of fans, ventilator orientation, efflux velocity and temperature of the emission point are presented within this table for reference purposes only.

### 3.4 Emission rate calculations and mass emission rates

The contaminant concentration from a stack is best quantified by a mass emission rate. For a chimney or ventilation stack, this is equal to the compound concentration ( $\mu\text{g}/\text{m}^3$  or  $\text{mg}/\text{m}^3$ ) of the discharge air multiplied by its flow-rate ( $\text{m}^3 \text{ s}^{-1}$ ). It is equal to the volume of air contaminated every second to the concentration limit ( $\text{g s}^{-1}$ ). The mass emission rate ( $\text{g s}^{-1}$ ) is used in conjunction with dispersion modelling in order to estimate the approximate radius of impact. All data used in the dispersion modelling exercise was obtained through library data. Tables 3.1 to 3.4 illustrates the overall volume flow values, mass emission rate values and general source characteristics used as input data to the model for each Scenario to estimate the radius of impact for the particular pollutant.

### 3.5 Dispersion modelling assessment

AERMOD Prime (21112) was used to determine the overall ground level impact of the pig farm emission points. These computations give the relevant GLC's at each 20 and 200 meter X Y Cartesian grid receptor location that is predicted to be exceeded for the specific air/odour quality impact criteria (fine and coarse grid assessment). A total Cartesian grid receptors of 4,086 points was established giving a total grid coverage area of 25 square kilometres around the emission points. In addition, individual sensitive receptors were also inputted into the model at 53 specific receptor points in the vicinity of the facility. 5 of these sensitive receptors represented Natura sites all of which are located circa 9.5 to 14 km from the site (see Figure 7.1 for local sensitive residential receptors only).

Five years of hourly sequential meteorological data from Shannon Airport (Shannon Airport 2016 to 2020 inclusive) and source characteristics (including emission data contained in Sections 3.1 to 3.2) were inputted into the dispersion model for all parameters.

### 3.6 Dispersion model Scenarios

AERMOD Prime (USEPA ver. 21112) was used to determine the overall odour and Ammonia air quality impact of the existing and proposed pig production facility operations.

Impacts from the emission points were assessed in accordance with the impact criterion contained in *Section 2.5 and 2.6*.

Four scenarios were assessed within the dispersion model. The output data was analysed to calculate the following:

#### **Ref Scenario 1 – Existing Odour impact (excluding background).**

- Predicted odour emission contribution of overall existing pig production facility operation (*see Table 3.1*), to odour plume dispersal at the 98<sup>th</sup> percentile for an odour concentration of less than or equal to 6.0  $\text{Ou}_E/\text{m}^3$  for worst case year 2017 (*see Figure 7.2*).

#### **Ref Scenario 2 – Proposed Odour impact (excluding background).**

- Predicted odour emission contribution of overall proposed pig production facility operation (*see Table 3.2*), to odour plume dispersal at the 98<sup>th</sup> percentile for an odour concentration of less than or equal to 3.0  $\text{Ou}_E/\text{m}^3$  for worst case year 2017 (*see Figure 7.3*).

#### **Ref Scenario 3A & 3B – Existing Ammonia impact (excluding background).**

##### **Scenario 3A**

- Predicted Ammonia emission contribution of overall existing pig production facility operation (*see Table 3.3*), to Ammonia plume dispersal at the 100<sup>th</sup> percentile 1 hr average for an Ammonia concentration of less than or equal to 50  $\mu\text{g}/\text{m}^3$  for worst case year 2017 (*see Figure 7.4*).

##### **Scenario 3B**

- Predicted Ammonia emission contribution of overall existing pig production facility operation (*see Table 3.3*), to Ammonia plume dispersal as an Annual average for an Ammonia concentration of less than or equal to 3.0  $\mu\text{g}/\text{m}^3$  for worst case year 2017 (*see Figure 7.5*).

#### **Ref Scenario 4A & 4B – Proposed Ammonia impact (excluding background).**

##### **Scenario 4A**

- Predicted Ammonia emission contribution of overall proposed pig production facility operation (*see Table 3.4*), to Ammonia plume dispersal at the 100<sup>th</sup> percentile 1 hr average for an Ammonia concentration of less than or equal to 275  $\mu\text{g}/\text{m}^3$  for worst case year 2017 (*see Figure 7.6*).

##### **Scenario 4B**

- Predicted Ammonia emission contribution of overall proposed pig production facility operation (*see Table 3.4*), to Ammonia plume dispersal as an Annual average for an Ammonia concentration of less than or equal to 6.0  $\mu\text{g}/\text{m}^3$  for worst case year 2017 (*see Figure 7.7*).

## 4. Discussion of Results from Dispersion modelling exercise

This section will present the discussion of results from the dispersion modelling assessment.

AERMOD GIS Pro Prime (Ver. 21112) was used to determine the overall proposed odour and Ammonia impact of the existing and proposed pig production facility operations.

One hour, Annual and Percentile averaging intervals were chosen to allow direct comparison of predicted GLC's with the relevant odour/Ammonia assessment criteria as outline in *Table 2.1*. In particular, 1-hour 98 percentile GLC's for odour were calculated at 20 and 200 metres grid distribution in the vicinity of the facility. For Ammonia, 1 hour and Annual average. A total Cartesian grid receptors of 4,086 points was established giving a total grid coverage area of 25 square kilometres around the emission points.

### 4.1 Odour impact

The plotted odour concentrations of  $\leq 6.0 \text{ Ou}_E/\text{m}^3$  for the 98<sup>th</sup> percentile for the existing pig production facility for worst case meteorological year 2017 is illustrated in *Figure 7.2*. As can be observed in *Figure 7.2*, the odour plume spread is approximately 150 to 200 m from the facility buildings. The maximum predicted ground level concentration of odour at the worst case sensitive receptor in the vicinity of the facility was less than or equal to  $0.79 \text{ Ou}_E/\text{m}^3$  for the 98<sup>th</sup> percentile of hourly averages for the worst case meteorological year (see *Table 4.1*). This is less than the guideline odour limit value (see *Table 4.1* and *Figure 7.2*).

The plotted odour concentrations of  $\leq 3.0 \text{ Ou}_E/\text{m}^3$  for the 98<sup>th</sup> percentile for the proposed pig production facility for worst case meteorological year 2017 is illustrated in *Figure 7.3*. As can be observed in *Figure 7.3*, the odour plume spread is approximately 1300 m from the facility buildings in a north westerly and north easterly direction. The maximum predicted ground level concentration of odour at the worst case sensitive receptor in the vicinity of the facility was less than or equal to  $2.64 \text{ Ou}_E/\text{m}^3$  for the 98<sup>th</sup> percentile of hourly averages for the worst case meteorological year (see *Table 4.1*). This is less than the guideline odour limit value (see *Table 4.1* and *Figure 7.3*).

**Table 4.1.** Predicted 98<sup>th</sup> percentile ground level concentrations of odour at receptor locations in the vicinity of the facility for the worst case meteorological year 2017 (see Figure 7.1 for locations).

## 4.2 Ammonia impact

The plotted Ammonia concentrations of  $\leq 50 \mu\text{g}/\text{m}^3$  for the 100<sup>th</sup> percentile for the existing pig production facility for worst case meteorological year 2017 is illustrated in *Figure 7.4*. As can be observed in *Figure 7.4*, the Ammonia plume spread is approximately 150 to 200 m from the facility buildings. The maximum predicted ground level concentration of Ammonia at the worst case sensitive receptor in the vicinity of the facility was less than or equal to  $31.42 \mu\text{g}/\text{m}^3$  for the 100<sup>th</sup> percentile of hourly averages for the worst case meteorological year (see *Table 4.2*). This is less than the guideline Ammonia limit value for the protection of human health (see *Table 4.2 and Figure 7.4*).

The Annual average ground level concentration for the existing pig production facility is present in the *Figure 7.5 and Table 4.2*. As can be observed in *Figure 7.5*, the Ammonia plume spread is approximately 100 m from the facility buildings. The maximum predicted ground level concentration of Ammonia at the worst case sensitive receptor in the vicinity of the facility was less than or equal to  $0.51 \mu\text{g}/\text{m}^3$  for the Annual averages for the worst case meteorological year 2017 (see *Table 4.2*). The maximum predicted ground level concentration at the identified Natura sites is less than  $0.014 \mu\text{g}/\text{m}^3$ . This is less than the guideline Ammonia limit value for the protection of ecosystems at these locations (see *Table 4.2 and Figure 7.5*).

The plotted Ammonia concentrations of  $\leq 100 \mu\text{g}/\text{m}^3$  for the 100<sup>th</sup> percentile for the proposed pig production facility for worst case meteorological year 2017 is illustrated in *Figure 7.6*. As can be observed in *Figure 7.6*, the Ammonia plume spread is approximately 300 m from the facility buildings in a north westerly direction. The maximum predicted ground level concentration of Ammonia at the worst case sensitive receptor in the vicinity of the facility was less than or equal to  $66.95 \mu\text{g}/\text{m}^3$  for the 100<sup>th</sup> percentile of hourly averages for the worst case meteorological year (see *Table 4.2*). This is less than the guideline Ammonia limit value for the protection of human health (see *Table 4.2 and Figure 7.6*).

The Annual average ground level concentration for the proposed pig production facility is present in the *Figure 7.7 and Table 4.2*. As can be observed in *Figure 7.7*, the Ammonia plume spread is approximately 200 to 250 m from the facility buildings in a north westerly and north easterly direction. The maximum predicted ground level concentration of Ammonia at the worst case sensitive receptor in the vicinity of the facility was less than or equal to  $3.0 \mu\text{g}/\text{m}^3$  for the Annual averages for the worst case meteorological year 2017 (see *Table 4.2*). The maximum predicted ground level concentration at the identified Natura sites is less than or equal to  $0.04 \mu\text{g}/\text{m}^3$ . This is 4% of the Critical exposure limit value of  $1 \mu\text{g}/\text{m}^3$  for Ammonia for the protection of sensitive ecosystems at these locations (see *Table 4.2 and Figure 7.7*).

**Table 4.2.** Predicted 1 hr max and Annual average ground level concentrations of Ammonia at receptor locations in the vicinity of the facility and at Natura sites for the worst case meteorological year 2017 (see Figure 7.1 for locations).

## 5. Conclusions

The following conclusions were drawn from the dispersion modelling assessment: Greater detail can be found within the document and it is recommended that the document be read in full. The main conclusions include:

- Dispersion modelling of Odour and Ammonia emissions from the existing and proposed pig production facility was performed in accordance with AG4 and best international practice with a minimum of five years of hourly sequential meteorological data used in the dispersion modelling assessment. Topographical data from Ordnance Survey Ireland was also inputted into the dispersion model in order to take account of the terrain effects in the vicinity of the site. In addition, sensitive receptors were included within the dispersion model in order to predict the level of pollutants at their specific location.
- Worst case referenced library odour and NH<sub>3</sub> emission data was utilised to develop the odour and NH<sub>3</sub> emission dataset for the existing and proposed facility. This was to remain conservative within the assessment.
- With regards to the existing pig production facility operations, the odour plume spread is approximately 150 to 200 m from the facility buildings (see *Figure 7.2*). The maximum predicted ground level concentration of odour at the worst case sensitive receptor in the vicinity of the facility was less than or equal to 0.79 Ou<sub>E</sub>/m<sup>3</sup> for the 98<sup>th</sup> percentile of hourly averages for the worst case meteorological year (see *Table 4.1*). This is less than the guideline odour limit value of less than or equal to 6.0 Ou<sub>E</sub>/m<sup>3</sup> for the 98<sup>th</sup> percentile of hourly averages (see *Table 4.1 and Figure 7.2*).
- With regards to the proposed pig production facility operations, the odour plume spread is approximately 1,300 m from the facility buildings in a north westerly and north easterly direction (see *Figure 7.3*). The maximum predicted ground level concentration of odour at the worst case sensitive receptor in the vicinity of the facility was less than or equal to 2.64 Ou<sub>E</sub>/m<sup>3</sup> for the 98<sup>th</sup> percentile of hourly averages for the worst case meteorological year (see *Table 4.1*). This is less than the guideline odour limit value of less than or equal to 6.0 Ou<sub>E</sub>/m<sup>3</sup> for the 98<sup>th</sup> percentile of hourly averages (see *Table 4.1 and Figure 7.3*).
- With regards to the existing pig production facility operations, the Ammonia plume spread for the 100<sup>th</sup> percentile 1 hour maximum ground level concentration is approximately 150 to 200 m from the facility buildings (see *Figure 7.4*). The maximum predicted ground level concentration of Ammonia at the worst case sensitive receptor in the vicinity of the facility was less than or equal to 31.42 µg/m<sup>3</sup> for the 100<sup>th</sup> percentile of hourly averages for the worst case meteorological year (see *Table 4.2*). This is less than the guideline Ammonia limit value for the protection of human health (see *Table 4.2 and Figure 7.4*).
- With regards to the existing pig production facility operations, the Ammonia plume spread for the Annual average ground level concentration is approximately 100 m from the facility buildings. The maximum predicted ground level concentration of Ammonia at the worst case sensitive receptor in the vicinity of the facility was less than or equal to 0.51 µg/m<sup>3</sup> for the Annual averages for the worst case meteorological year 2017 (see *Table 4.2*). The maximum predicted ground level concentration at the identified Natura sites is less than 0.014 µg/m<sup>3</sup>. This is less than the guideline Ammonia limit value for the protection of ecosystems at these locations (see *Table 4.2 and Figure 7.5*).
- With regards to the proposed pig production facility operations, the Ammonia plume spread for the 100<sup>th</sup> percentile 1 hour maximum ground level concentration is approximately 300 m from the facility buildings in a north easterly direction. The maximum predicted ground level concentration of Ammonia at the worst case sensitive receptor in the vicinity of the facility was less than or equal to 66.95 µg/m<sup>3</sup> for the 100<sup>th</sup> percentile of hourly averages for the worst case meteorological year (see

*Table 4.2*). This is less than the guideline Ammonia limit value for the protection of human health (see *Table 4.2 and Figure 7.6*).

- With regards to the proposed pig production facility operations, the Ammonia plume spread for the Annual average ground level concentration is approximately 200 to 250 m from the facility buildings in a north westerly and north easterly direction. The maximum predicted ground level concentration of Ammonia at the worst case sensitive receptor in the vicinity of the facility was less than or equal to  $3.0 \mu\text{g}/\text{m}^3$  for the Annual averages for the worst case meteorological year 2017 (see *Table 4.2*). The maximum predicted ground level concentration at the identified Natura sites is less than or equal to  $0.04 \mu\text{g}/\text{m}^3$ . This is 4% of the Critical exposure limit value of  $1 \mu\text{g}/\text{m}^3$  for Ammonia for the protection of sensitive ecosystems at these locations (see *Table 4.2 and Figure 7.7*).
- With regards to the proposed facility operations, the facility operations will be in compliance with the guideline Odour and Ammonia impact presented within the document.

### 7. Appendix I - Contour plots for dispersion modelling assessment

Odour and Ammonia contour plots are illustrated in this section. Contour plots are only supplied in this section for illustrative purposes only.

#### 7.1. Site layout and location

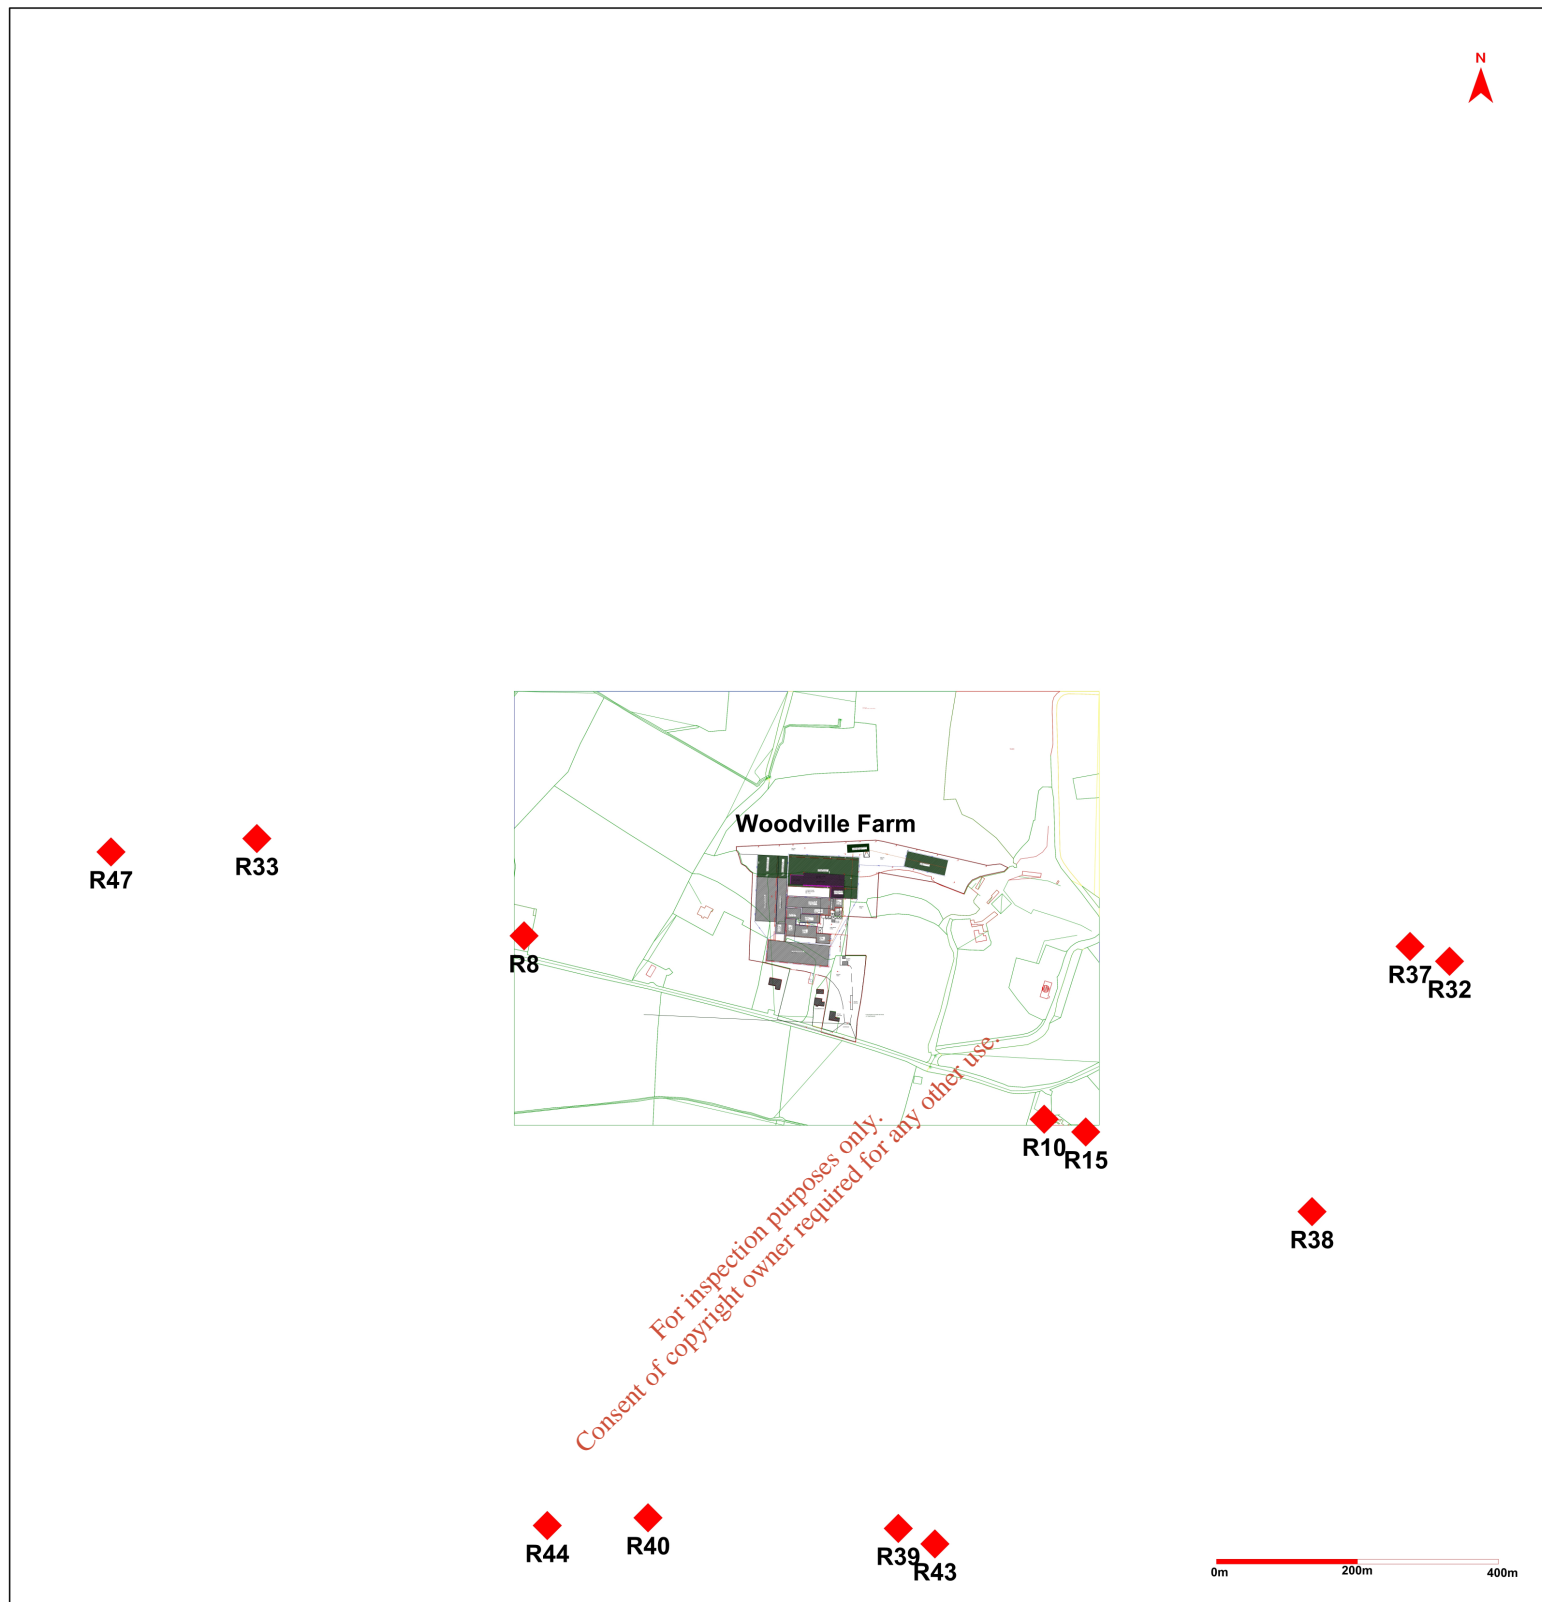

Figure 7.1. Aerial facility layout map showing relative location of the pig production facility, Woodville Farms with sensitive receptors.

7.2. Dispersion modelling contour plots for – Odour: REF SCENARIO 1 Existing

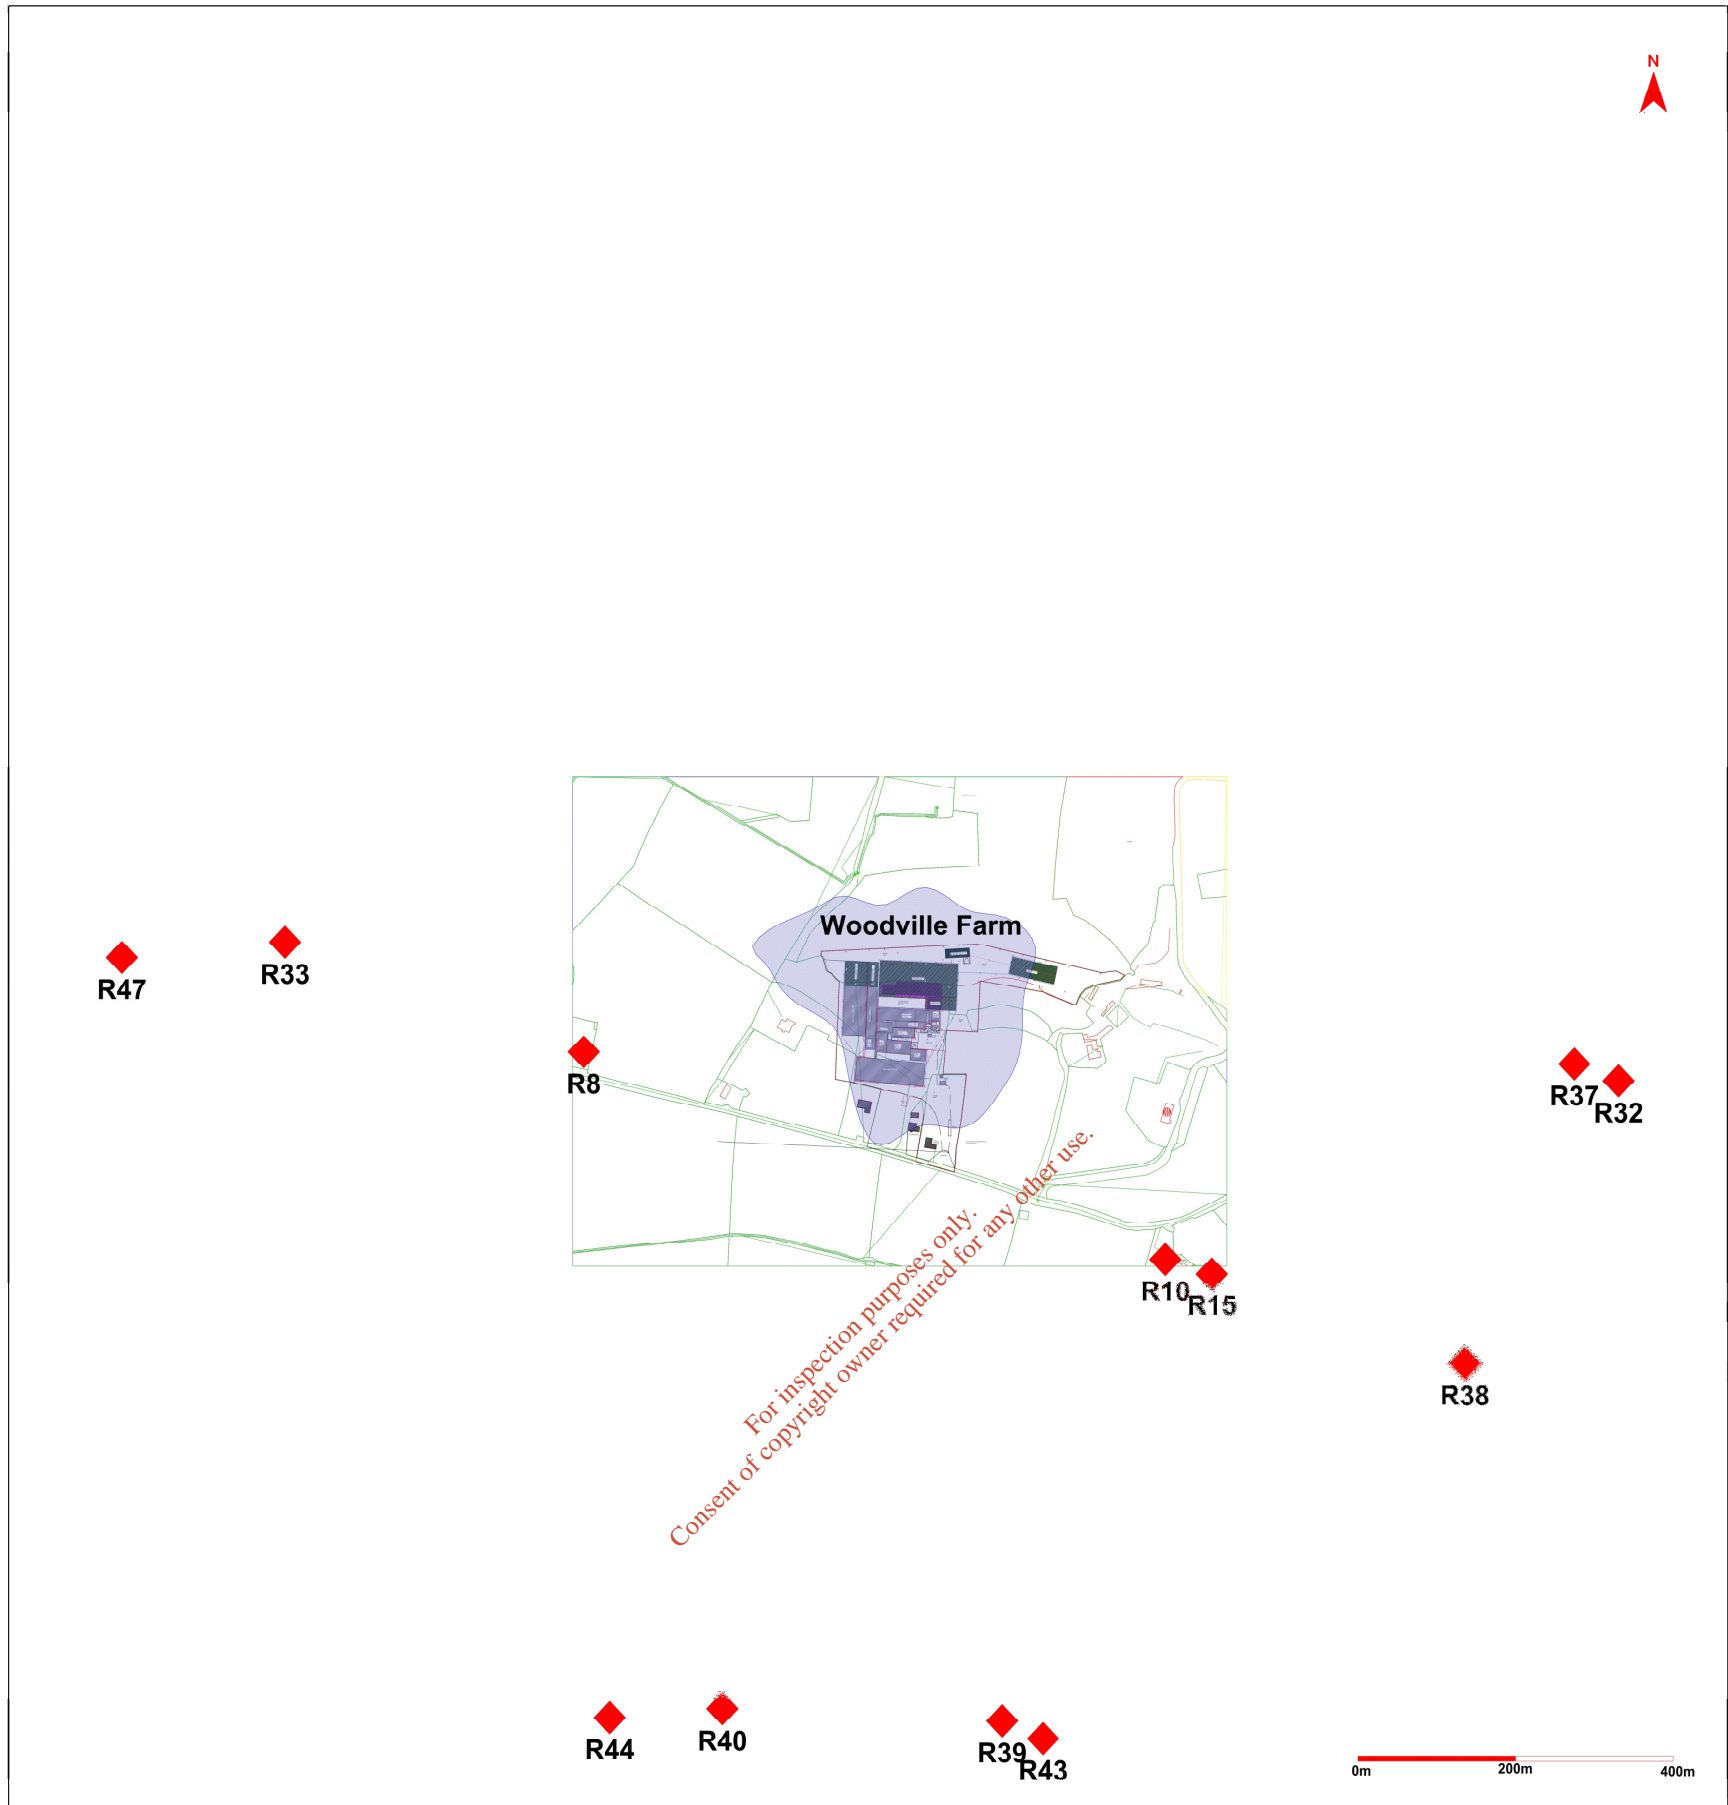

Figure 7.2. Predicted odour plume spread of the existing pig fattening facility for at the 98<sup>th</sup> percentile of hourly averages for an odour concentrations of  $\leq 6.0 \text{ Ou}_E/\text{m}^3 \text{ yr 2017}$  ( — ).

7.3. Dispersion modelling contour plots for – Odour: REF SCENARIO 2 Proposed

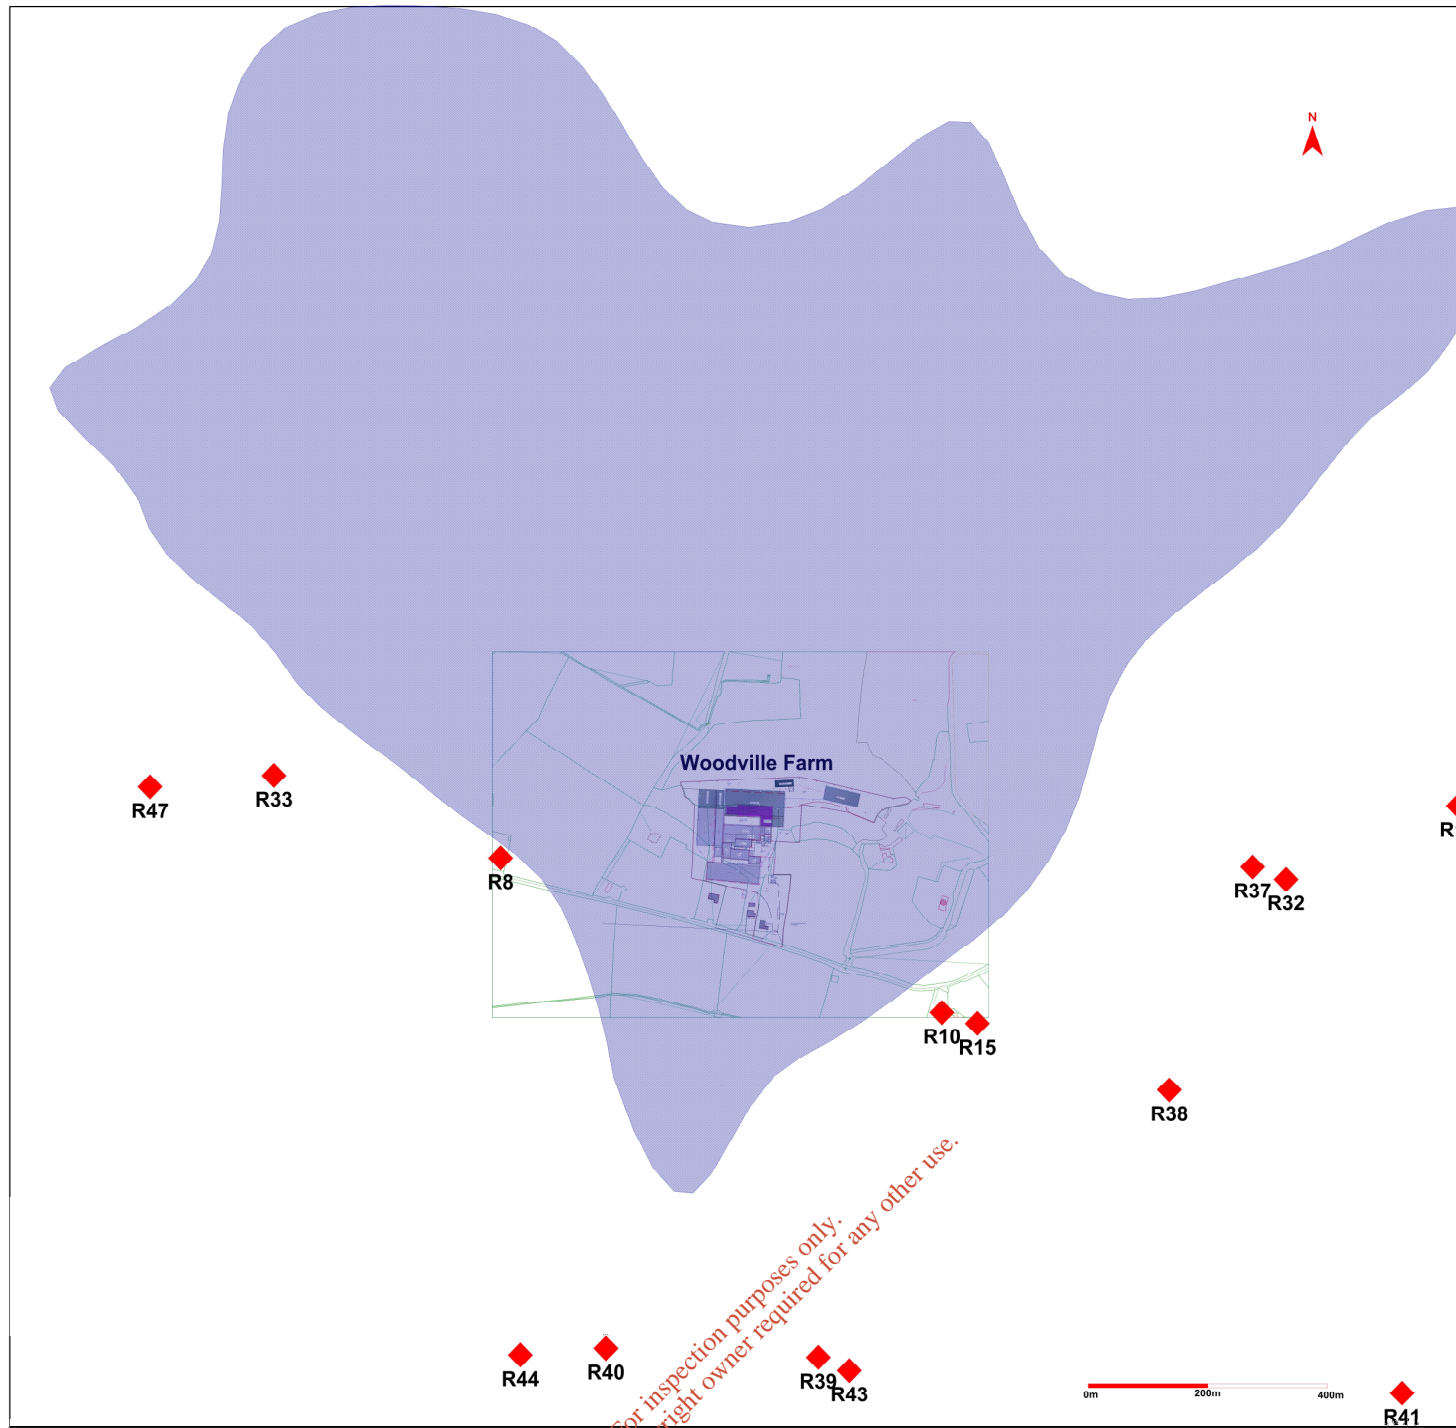

Figure 7.3. Predicted odour plume spread of the proposed pig fattening facility for at the 98<sup>th</sup> percentile of hourly averages for an odour concentrations of  $\leq 3.0 \text{ Ou}_E/\text{m}^3 \text{ yr } 2017$  ( — ).

7.4. Dispersion modelling contour plots Ref Scenario 3A - Existing 1 hr max Ammonia impact (excluding background).

Figure 7.4. Predicted Ammonia plume spread of the existing pig fattening facility for the 100<sup>th</sup> percentile of hourly averages for an Ammonia concentrations of  $\leq 50 \mu\text{g}/\text{m}^3$  yr 2017 ( — ).

7.4. Dispersion modelling contour plots Ref Scenario 3B - Existing Annual Average max Ammonia impact (excluding background).

Figure 7.5. Predicted Ammonia plume spread of the existing pig fattening facility for the Annual averages Ammonia concentrations of  $\leq 3.0 \mu\text{g}/\text{m}^3$  yr 2017 (■).

7.5. Dispersion modelling contour plots Ref Scenario 4A - Proposed 1 hr max Ammonia impact (excluding background).

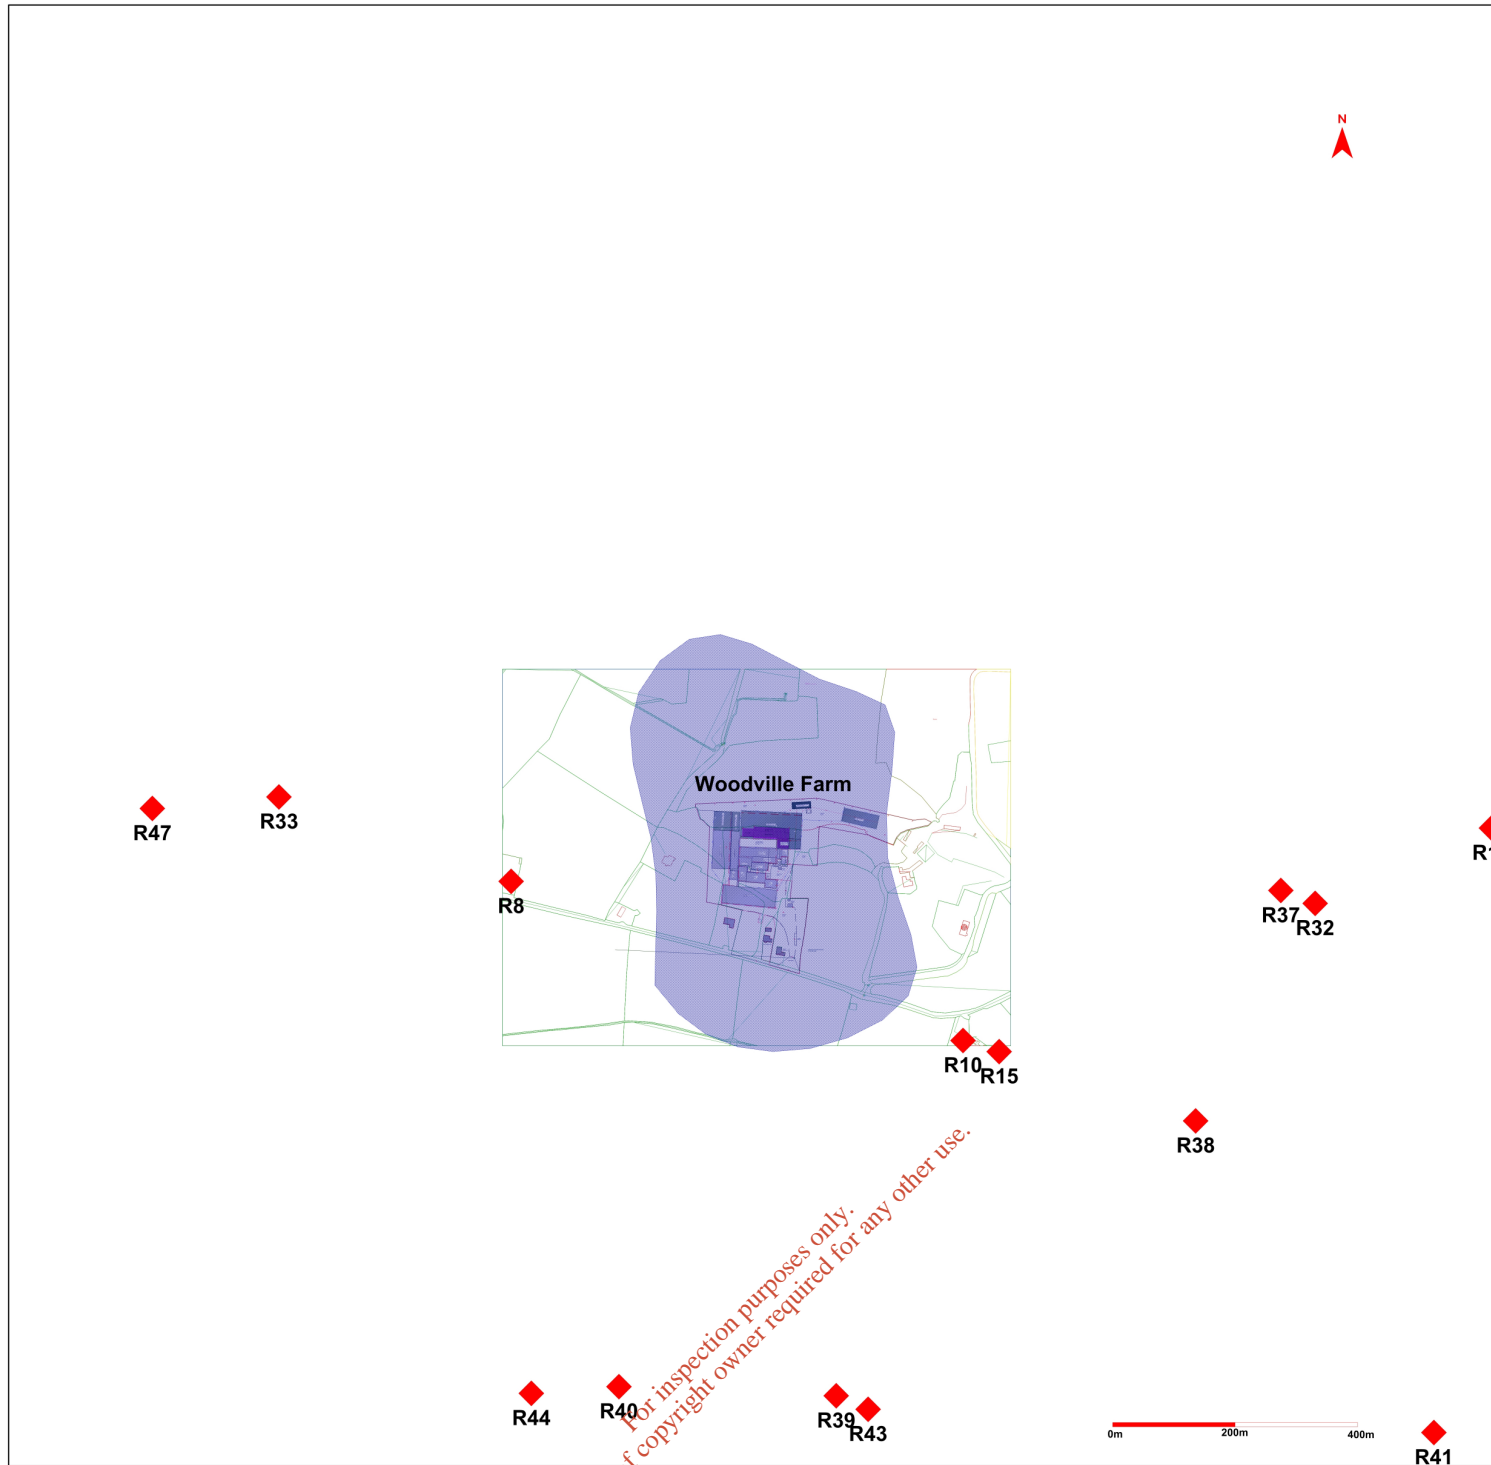

Figure 7.6. Predicted Ammonia plume spread of the proposed pig fattening facility for the 100<sup>th</sup> percentile of hourly averages for an Ammonia concentrations of  $\leq 100 \mu\text{g}/\text{m}^3$  yr 2017 ( — )

7.6. Dispersion modelling contour plots Ref Scenario 4B - Proposed Annual Average max Ammonia impact (excluding background).

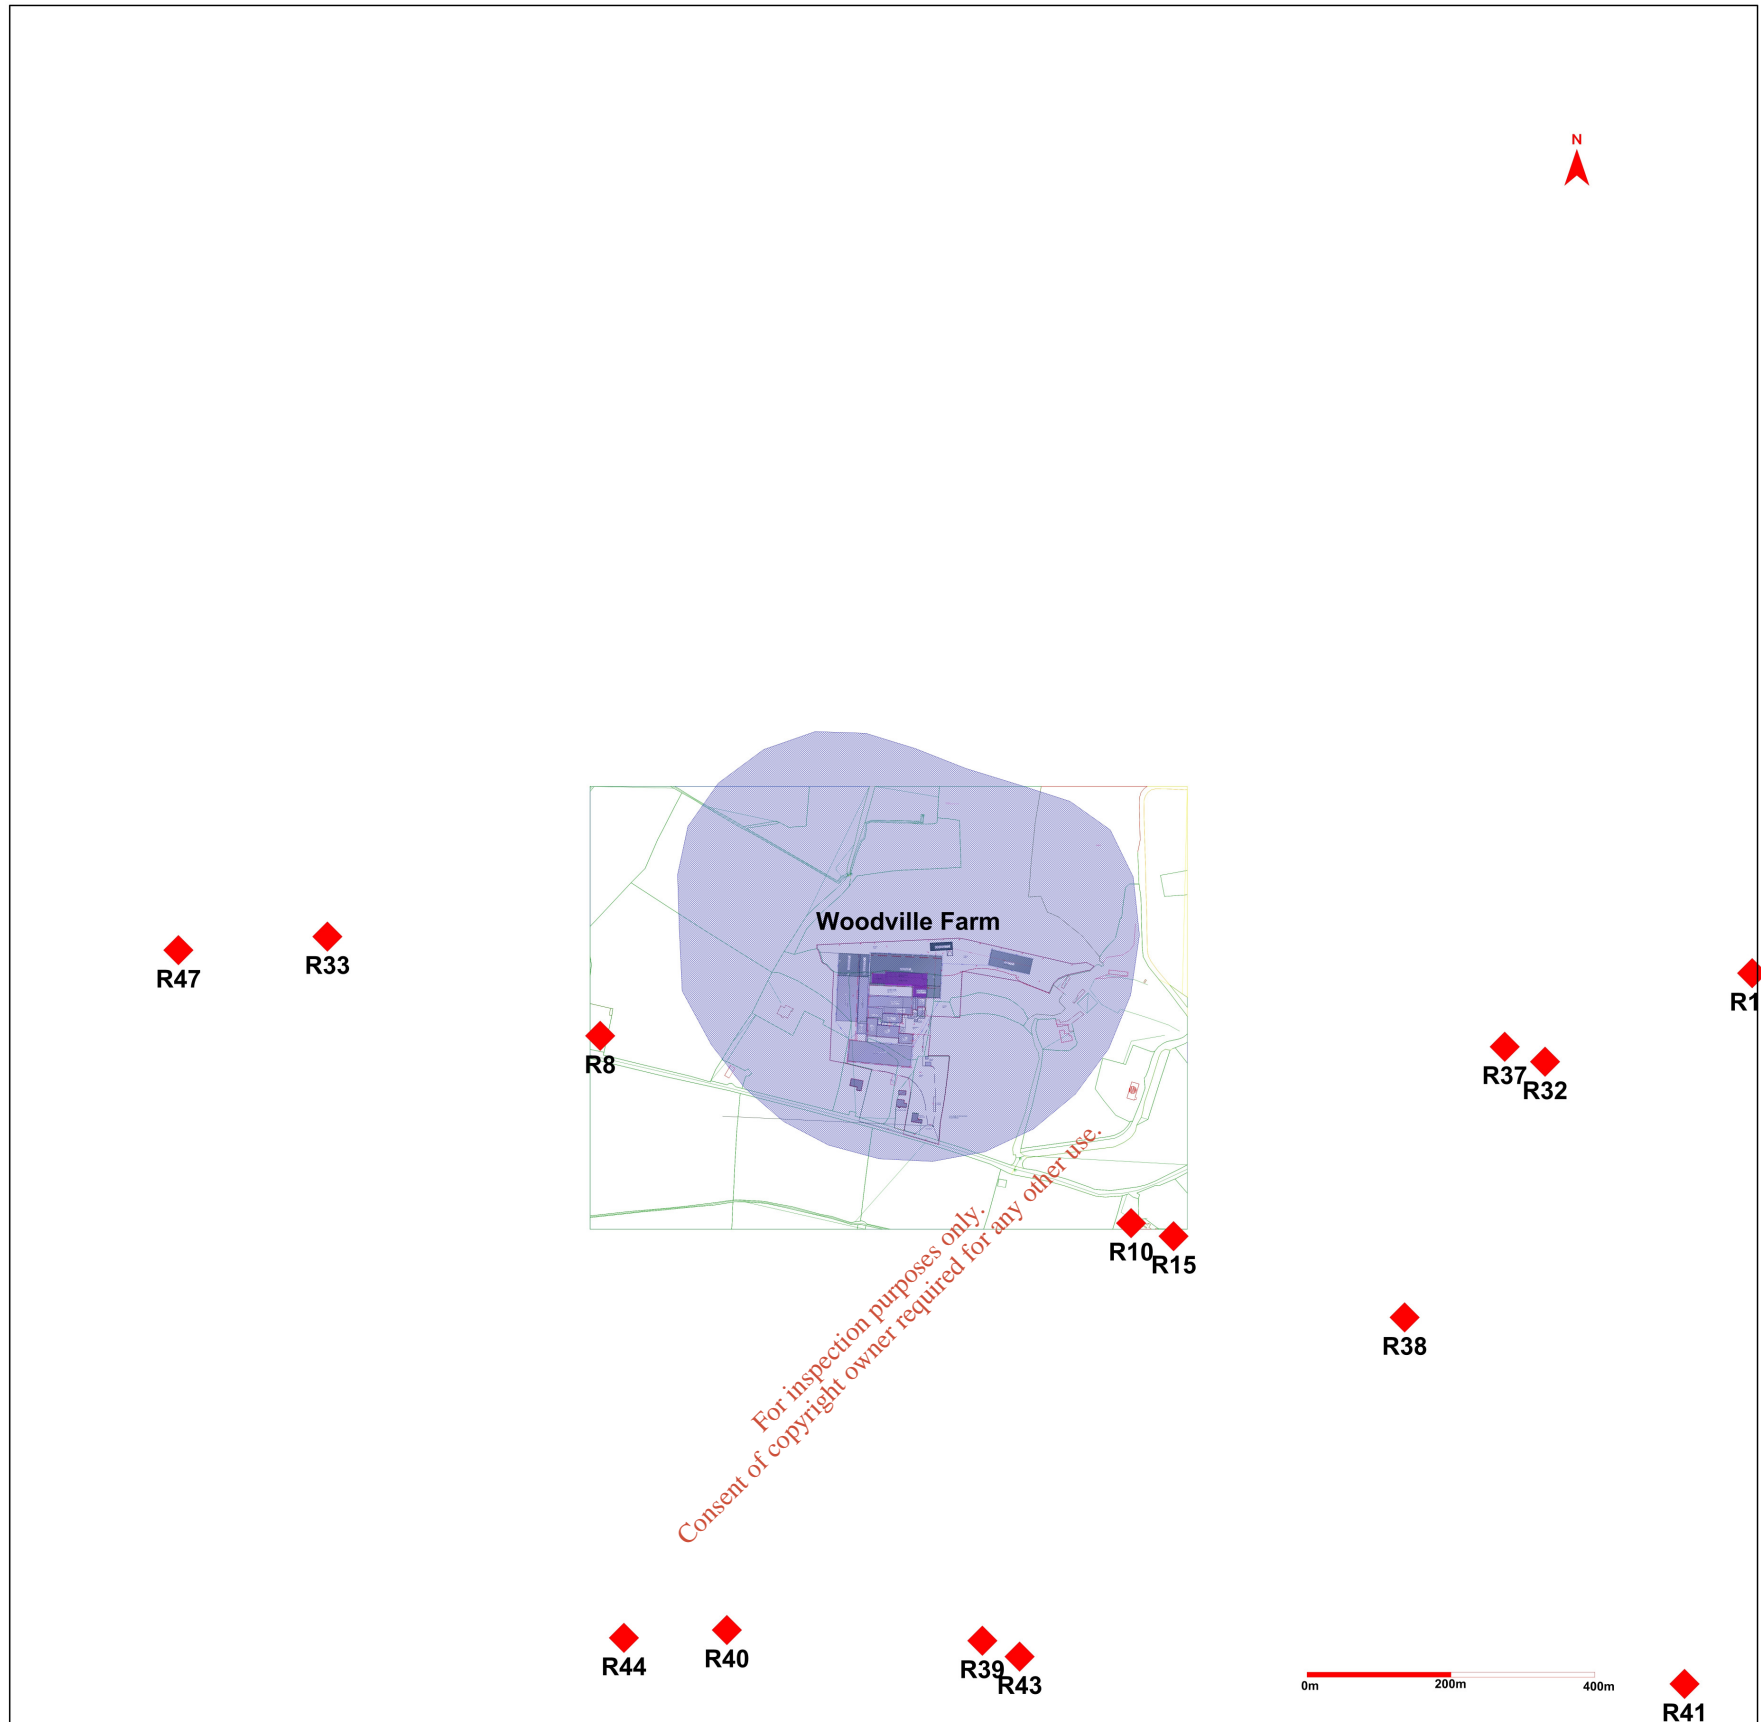

Figure 7.7. Predicted Ammonia plume spread of the proposed pig fattening facility for the Annual averages Ammonia concentrations of  $\leq 3.0 \mu\text{g}/\text{m}^3$  yr 2017 ( ).

## 8. Appendix II - Meteorological data used within the Dispersion modelling study.
